This Index has been prepared as part of the programme of the Technical Information Panel of AGARD.

THE MISSION OF AGARD

The mission of AGARD is to bring together the leading personalities of the NATO nations in the fields of science and technology relating to aerospace for the following purposes:

- Exchanging of scientific and technical information;

- Continuously stimulating advances in the acrospace sciences relevant to strengthening the common defence posture;
- Improving the co-operation among member nations in aerospace research and development;
- -- Providing scientific and technical advice and assistance to the North Atlantic Military Committee in the field of aerospace research and development;
- Rendering scientific and technical assistance, as requested, to other NATO bodies and to member nations in connection with research and development problems in the aerospace field;
- Providing assistance to member nations for the purpose of increasing their scientific and technical potential;
- Recommending effective ways for the member nations to use their research and development capabilities for the common benefit of the NATO community.

The highest authority within AGARD is the National Delegates Board consisting of officially appointed senior representatives from each member nation. The mission of AGARD is carried out through the Panels which are composed of experts appointed by the National Delegates, the Consultant and Exchange Program and the Aerospace Applications Studies Program. The results of AGARD work are reported to the member nations and the NATO Authorities through the AGARD series of publications of which this is one.

Participation in AGARD activities is by invitation only and is normally limited to citizens of the NATO nations.

The content of this publication has been reproduced directly from material supplied by AGARD or the authors.

PREFACE

This volume provides abstracts and indexes for AGARD publications published during the period 1974 – 1976. By an arrangement with the US National Aeronautics and Space Administration in Washington, the NASA computerized data base has been used to prepare this publication.

Full bibliographic citations and abstracts for all the documents in this publication are given in the abstract section, which is organized in the 10 major subject divisions and 74 specific categories used by NASA in its abstract journals and bibliographies. The major subject divisions are listed in the Table of Contents, together with a note for each that defines its scope and provides any cross-references. Category breaks in the abstract section are identified by category number and title, and a scope note. Within each category, the abstracts are arranged by series and year. N10,000 series (STAR) items appear before X70,000 series items. Examples of typical citations with abstracts are given following the Table of Contents.

There are five indexes: Subject, based on NASA Thesaurus nomenciature; Personal Author; Corporate Source; Report/Accession Number; and Accession/Report Number. Sample entries are shown on the first page of each index.

There are now five volumes in the current AGARD Index Series

TABLE OF CONTENTS Part 1: Abstracts

AERONAUTICS

Includes aeronautics (general); aerodynamics; air transportation and safety; aircraft communications and navigation; aircraft design, testing and performance; aircraft instrumentation; aircraft propulsion and power; aircraft stability and control; and research and support facilities (air).

For related information see also Astronautics.

01 AERONAUTICS (GENERAL)

02 AERODYNAMICS

Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery.

For related information see also 34 Fluid Mechanics and Heat Transfer.

03 AIR TRANSPORTATION AND SAFETY

Includes passenger and cargo air transport operations; and aircraft accidents.

For related information see also 16 Space Transportation and 85 Urban Technology and Transportation.

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION 4

Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control.

For related information see also 17 Spacecraft Communications, Command and Tracking and 32 Communications.

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE 64

includes aircraft simulation technology.

For related information see also 18 Spacecraft Design, Testing and Performance and 39 Structural Mechanics.

06 AIRCRAFT INSTRUMENTATION

Includes cockpit and cabin display devices; and flight instruments.

For related information see also 19 Spacecraft Instrumentation and 35 Instrumentation and Photography.

07 AIRCRAFT PROPULSION AND POWER 8

Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and on-board auxiliary power plants for aircraft.

For related information see also 20 Spacecraft Propulsion and Power, 28 Propellants and Fuels, and 44 Energy Production and Conversion.

08 AIRCRAFT STABILITY AND CONTROL 102

Includes aircraft handling qualities; piloting; flight controls; and autopilots.

09 RESEARCH AND SUPPORT

FACILITIES (AIR)

109

Includes airports, hangers and runways; aircraft repair and overhaul facilities; wind tunnels; shock tube facilities; and engine test blocks.

For related information see also 14 Ground Support Systems and Facilities (Space).

ASTRONAUTICS

23

Includes astronautics (general); astrodynamics; ground support systems and facilities (space); launch vehicles and space vehicles; space transportation; spacecraft communications, command and tracking; spacecraft design, testing and performance; spacecraft instrumentation; and spacecraft propulsion and power.

For related information see also Aeronautics.

12 ASTRONAUTICS (GENERAL)

N.A.

For extraterrestrial exploration see 91 Lunar and Planetary Exploration.

13 ASTRODYNAMICS

N.A.

Includes powered and free-flight trajectories; and orbit and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE)

NΔ

Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators.

For related information see also 09 Research and Support Facilities (Air).

15 LAUNCH VEHICLES AND SPACE VEHICLES

N.A.

Includes boosters; manned orbital laboratories; reusable vehicles; and space stations.

16 SPACE TRANSPORTATION

N.A.

Includes passenger and cargo space transportation, e.g., shuttle operations; and rescue techniques.

For related information see also 03 Air Transportation and Safety and 85 Urban Technology and Transportation.

17 SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING

N.A.

Includes telemetry; space communications networks; astronavigation; and radio blackout.

For related information see also 04 Aircraft Communications and Navigation and 32 Communications.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE

N.A.

Includes spacecraft thermal and environmental control; and attitude control.

For life support systems see 54 Man/System Technology and Life Support. For related information see also 05 Aircraft Design, Testing and Performance and 39 Structural Mechanics.

19 SPACECRAFT INSTRUMENTATION N.A

For related information see also 06 Aircraft Instrumentation and 35 Instrumentation and Photography.

20 SPACECRAFT PROPULSION AND POWER

Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources.

For related information see also 07 Aircraft Propulsion and Power, 28 Propellants and Fuels, and 44 Energy Production and Conversion.

CHEMISTRY AND MATERIALS

Includes chemistry and materials (general); composite materials; inorganic and physical chemistry; metallic materials; nonmetallic materials; and propellants and fuels.

23 CHEMISTRY AND MATERIALS (GENERAL)

Includes biochemistry and organic chemistry.

24 COMPOSITE MATERIALS Includes laminates.

25 INORGANIC AND PHYSICAL CHEMISTRY

Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photo-

For related information see also 77 Thermodynamics and Statistical Physics.

26 METALLIC MATERIALS

13

129

130

128

Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS 14

Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials.

28 PROPELLANTS AND FUELS 144

Includes rocket propellants, igniters, and oxidizers, storage and handling; and aircraft fuels.

For related information see also 07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power, and 44 Energy Production and Conversion.

ENGINEERING

Includes engineering (general); communications; electronics and electrical engineering; fluid mechanics and heat transfer; instrumentation and photography; lasers and masers; mechanical engineering; quality assurance and reliability; and structural mechanics. For related information see also *Physics*.

31 ENGINEERING (GENERAL) 1

Includes vacuum technology; control engineering; display engineering; and cryogenics.

32 COMMUNICATIONS

166

Includes land and global communications: communications theory; and optical communications.

For related information see also 04 Aircraft Communications and Navigation and 17 Spacecraft Communications, Command and Tracking.

33 ELECTRONICS AND ELECTRICAL ENGINEERING

169

Includes test equipment and maintainability, components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry

For related information see also 60 Computer Operations and Hardware and 76 Solid-State Physics.

34 FLUID MECHANICS AND HEAT TRANSFER

176

Includes boundary layers; hydrodynamics; fluidics; mass transfer; and ablation cooling.

For related information see also 02 Aerodynamics and 77 Thermodynamics and Statistical Physics.

35 INSTRUMENTATION AND PHOTOGRAPHY

104

Includes remote sensors; measuring instruments and gages; detectors; cameras and photographic supplies; and holography.

For aerial photography see 43 Earth Resources. For related information see also 06 Aircraft Instrumentation and 19 Spacecraft Instrumentation.

36 LASERS AND MASERS

185

Includes parametric amplifiers.

37 MECHANICAL ENGINEERING

Includes auxiliary systems (non-power); machine elements and processes, and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY

188

Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS

400

Includes structural element design and weight analysis; fatigue; and thermal stress.

For applications see O5 Aircraft Design, Testing and Performance and 18 Spacecraft Design, Testing and Performance.

GEOSCIENCES

Includes geosciences (general); earth resources, energy production and conversion; environment pollution; geophysics; meteorology and climatology, and oceanography.

For related information see also Space Sciences.

42 GEOSCIENCES (GENERAL)

N.A.

43 EARTH RESOURCES

Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial

For instrumentation see 35 Instrumentation and Photography.

44 ENERGY PRODUCTION AND CONVERSION

includes specific energy conversion systems, e.g., fuel cells and batteries; global sources of energy; fossil fuels; geophysical conversion; hydroelectric power; and wind power.

For related information see also O7 Aircraft: Propulsion and Power, 20 Spacecraft Propulsion and Power, 28 Propellants and Fuels, and 85 Urban Technology and Transportation.

46 ENVIRONMENT POLLUTION

Includes air, noise, thermal and water pollution; environment monitoring; and contamination control.

46 GEOPHYSICS

Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism

For space radiation see 93 Space Radiation.

47 METEOROLOGY AND CLIMATOLOGY N.A. Includes weather forecasting and modification.

48 OCEANOGRAPHY

Includes biological, dynamic and physical oceanography; and marine resources.

LIFE SCIENCES

Includes life sciences (general); aerospace medicine; behavioral sciences; man/system technology and life support; and planetary biology.

51 LIFE SCIENCES (GENERAL)

209

Includes genetics.

52 AEROSPACE MEDICINE 222

Includes physiological factors; biological effects of radiation; and weightlessness.

53 BEHAVIORAL SCIENCES

Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND

LIFE SUPPORT

Includes human engineering; biotechnology; and space suits and protective clothing.

55 PLANETARY BIOLOGY

N.A.

Includes exobiology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

Includes mathematical and computer sciences (general); computer operations and hardware; computer programming and software; computer systems; cybernetics; numerical analysis; statistics and probability; systems analysis; and theoretical mathematics.

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL)

243

60 COMPUTER OPERATIONS AND HARDWARE

Includes computer graphics and data processing. For components sue 32 Electronics and Electrical Engineering.

61 COMPUTER PROGRAMMING AND SOFTWARE

N.A.

Includes computer programs, routines, and algorithms.

62 COMPUTER SYSTEMS

245

Includes computer networks.

63 CYBERNETICS

N.A.

includes feedback and control theory. For related information see also 54 Man/System Technology and Life Support.

54 NUMERICAL ANALYSIS

N.A.

Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY

N.A.

Includes data sampling and smoothing: Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS

N.A.

Includes mathematical modeling; network analysis. and operations research.

67 THEORETICAL MATHEMATICS

N.A.

Includes topology and number theory.

PHYSICS

Includes physics (general); acoustics; atomic and molecular physics; nuclear and high-energy physics, optics; plasma physics; solid-state physics; and thermodynamics and statistical physics.

For related information see also Engineering.

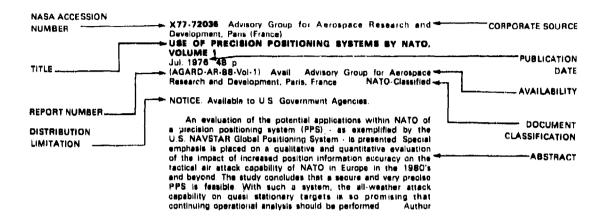

70 PHYSICS (GENERAL)

For geophysics see 46 Geophysics. For astrophysics see 90 Astrophysics. For solar physics see 92 Solar Physics.

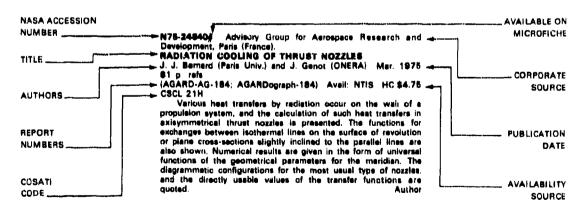

71 ACOUSTICS 256 Includes sound generation, transmission, and	83 ECONOMICS AND COST ANALYSIS 269 Includes cost effectiveness studies.
attenuation. For noise pollution see 45 Environment Pollution.	84 LAW AND POLITICAL SCIENCE N.A. Includes space law; international law; international
72 ATOMIC AND MOLECULAR PHYSICS N.A. Includes atomic structure and molecular spectra.	cooperation; and patent policy.
73 NUCLEAR AND HIGH-ENERGY PHYSICS N.A. Includes elementary and nuclear particles; and reactor theory. For space radiation see 93 Space Radiation. 74 OPTICS 260 Includes light phenomena.	85 URBAN TECHNOLOGY AND TRANSPORTATION 270 Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see 03 Air Transportation and Safety, 16 Space Transportation, and 44 Energy Production and Conversion.
75 PLASMA PHYSICS N.A. Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see 46 Geophysics. For space plasmas see 90 Astrophysics.	SPACE SCIENCES Includes space sciences (general); astronomy; astrophysics; lunar and planetary exploration; solar physics; and space radiation. For related information see also Geosciences.
76 SOLID-STATE PHYSICS N.A. Includes superconductivity.	88 SPACE SCIENCES (GENERAL) N.A.
For related information see also 33 Electronics and Electrical Engineering and 36 Lasers and Masers.	89 ASTRONOMY N.A. Includes radio and gamma-ray astronomy; celestial mechanics; and astrometry.
77 THERMODYNAMICS AND STATISTICAL PHYSICS N.A. Includes quantum mechanics; and Bose and Fermi statistics.	90 ASTROPHYSICS N.A, Includes cosmology; and interstellar and interplanetary gases and dust.
For related information see also 25 Inorganic and Physical Chemistry and 34 Fluid Mechanics and Heat Transfer.	91 LUNAR AND PLANETARY EXPLORATION N.A, Includes planetology; and manned and unmanned flights.
SOCIAL SCIENCES Includes social sciences (general); administration and management; documentation and information	For spacecraft design see 18 Spacecraft Design, Testing and Performance. For space stations see 15 Launch Vehicles and Space Vehicles.
science; economics and cost analysis; law and political science; and urban technology and transportation.	92 SOLAR PHYSICS N.A. Includes solar activity, solar flares, solar radiation and superpote
80 SOCIAL SCIENCES (GENERAL) Includes educational matters.	and sunspots. 93 SPACE RADIATION N.A.
81 ADMINISTRATION AND MANAGEMENT 262 Includes management planning and research.	Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see 52 Aerospace Medicine. For theory see 73 Nuclear and High-Energy.
82 DOCUMENTATION AND INFORMATION SCIENCE 263 Includes Information storage and retrieval technol-	Physics. GENERAL

AGARD INDEX OF PUBLICATIONS (1974 - 1976)

ABSTRACT SECTION

01 AERONAUTICS (GENERAL)

N75-14710# Advisory Group for Aerospace Research and Development, Paris (France)

AGARD HIGHLIGHTS, MARCH 1974

Mar 1974 30 p

(AGARD-Highlights-74/1) Avail. NTIS HC \$3.75

The activities and accomplishments of the Advisory Group for Aerospace Research and Development (AGARD) during the first quarter of 1974 are discussed. Some of the subjects considered are (1) using science and technology to meet military requirements at reduced cost. (2) preliminary design applications for reducing development, production, and operational costs of aircraft systems, (3) atmosphere pollution by aircraft engines, and (4) design and development of large wind tunnels

N75-14711∦ Advisory Group for Aerospace Rosearch and Davelopment, Paris (France) THE PERKINS GLASSER LECTURES, MARCH 1974 Sep 1974 27 p in ENGLISH, partly in FRENCH

(AGARD-Highlights-74/2) Avail NTIS HC \$3.75 An address to the Advisory Group for Aerospace Research and Development (AGARD) which was delivered in September, 1974 is presented. The subject of the address is the Impact of Research and Development on the United States Air Force. Some of the topics considered in the address are (1) the National support of research, (2) basic and applied research in the Air Force, (3) development of inertial guidance systems, and (4) development of electronic digital computer. Areas of interest involved the methods for funding research and development activities and the process for making new technology available to industry

N75-21219# Advisory Group for Aerospace Research and Development, Paris (France)

TAKE-OFF AND LANDING
Jan 1975 300 p refs Presented at 44th Meeting of the
Flight Mech. Panel of AGARD, Edinburgh, 1-4 Apr. 1974
(AGARD-CP-180) Avail NTIS HC \$8.75

The proceedings of a conference on aircraft takeoff and landing are presented. The subjects discussed include the following: (1) aircraft design optimization, (2) energy management, (3) aircraft stability and control characteristics, (4) aircraft guidance using ground based and airborne aggipment, and (5) operational aspects of approach control with short takeoff aircraft. For individual titles, see N75-21220 through N75-21241

N75-21220* National Aeronautics and Space Administration Langley Research Center, Langley Station, Va. HIGH-LIFT AERODYNAMICS: TRENDS, TRADES, AND

Richard J. Margason and Harry L. Morgan, Jr. In AGARD. Take-off and Landing Jan. 1975 11 p refs (For availability see N75-21219 13.01)

The trend toward the utilization of higher maximum lift coefficient with increased alteraft size and cruise velocities is discussed. The impact of this trend on the need for tradeoffs between cruise performance and takeoff, climb, and landing performance is examined. Theoretical methods for the analysis of the two-dimensional characteristics of flap systems are described and compared with experimental data. Four powered-lift

concepts are described to outline some of the options currently being developed. Two jet flap theories are described which provide analytical methods for estimation of the three-dimensional aerodynamic high-lift performance characteristics of powered lift

N75-21221* Messerschmitt-Boelkow Blohm G.m.b.H., Munich

COMPATIBILITY OF TAKE OFF AND LANDING WITH MISSION AND MANOEUVRE PERFORMANCE REQUIRE MENTS FOR FIGHTER AIRCRAFT

Dieter Reich and Josef Wimbauer In AGARD Take-off und Landing Jan. 1875 7 p refs (For availability see N75-21219 13-01)

By means of an aircraft synthesis program, the effect of engine cycle, thrust to weight ratio, and wing parameter combination on field and flight performance has been investigated For three different engine /Intake configurations, thrust to weight ration and wing loading were varied. Each combination represents an aircraft designed to meet a specified mission radius. Using different lift systems and ground deceleration devices, the conditions are shown under which a matching of flight and field performance is economically feasible

N75-21222 Aerospatiale Usines de Toulouse (France). GENERAL CRITERIA FOR THE DEFINITION OF TAKE OFF AND LANDING OF AN AIRCRAFT WITH NONLIMITED LIFT [CRITERES GENERAUX POUR LA DEFINITION AU DECOLL-AGE ET A L'ATTERRISSAGE D'UN AVION NON LIMITE EN PORTANCE

C Pelagatti and T. Markham (British Aircraft Corp., Bristol, England) In AGARD Take-off and Landing Jan 1975 11 p In FRENCH (For availability see N75-21218 13-01)

The performance of a slender wing alteraft configuration with unlimited lift was studied. A description is given of the approach process, serodynamic characteristics, and certification regulations. The optimization of characteristics based on speed was developed after considering examples from the Concorde

N75-21223* Bosing Commercial Airplane Co., Seattle, Wash TERMINAL AREA CONSIDERATIONS FOR AN ADVANCED CTOL TRANSPORT AIRCRAFT

Mark B. Susaman In AGARD Take-off and Landing Jan. 1975 14 p. refs (For availability see N75-21219 13-01) (Contract NAS1-12018)

Projected future conditions at large urban sirports were used to identify design objectives for a long-hauf, advanced transport sirplans introduced for operation in the mid-1980s. Operating constraints associated with airport congestion and aircraft noise and emissions were of central interest. In addition, some of the interaction of these constraints with aircraft fuel usage were identified. The study sllowed for advanced aircraft design features consistent with the future operating period. A baseline 200 passenger simplene design was modified to comply with design requirements imposed by terminal area constraints. Specific design changes included: (1) modification of engine arrangement, wing planform; (2) drag and spoiler surfaces; (3) secondary power systems: (4) brake and landing gear characteristics; and (5) the aircraft avionics. These changes, based on exploratory design estimates and allowing for technology advance, were judged to enable the airplane to, reduce wake turbulence, handle steeper descent paths with fewer limitation due to engine characteristics; reduce runway occupancy times, improve community noise contours; and reduce the total engine emittants deposited in the terminal area. The populties to simplane performance and operating cost associated with improving the terminal area characteristics of the sirplane were assessed. Finally, key research problems requiring solution in order to validate the assumed advanced airplane technology were identified Author

N75-21224 Service Technique de l'Aeronautique, Pans (France) **BRAKING PERFORMANCES**

Georges Leblanc In AGARD Take-off and Landing Jan 1975 In FRENCH, ENGLISH summary (For availability see N75 21219 13 011

During Landing or aborted take off, the braking distances are depending on the speed allowed by high lift devices and on the Kinetic energy which must be absorbed by the braking systems according to the available friction coefficient of tire runway. Studies on this last point have not yet been so extensive as aerodynamic studies. Beside obvious interest for performances, it is necessary to know how to determine the safety margins which have to be taken on braking distances according to actual conditions of the runway. For the prediction of braking distance a comprehensive scheme of friction phenomena on wet runway according the three zone's GROUCH model is proposed. The test results obtained with CARAVELLE Aircraft confirm that the proposed model is correct and that it can give a satisfactory prediction of the braking

N75-21225 Air Force Flight Dynamics Lab , Wright-Patterson AFB, Ohio

TRADEOFF PARAMETERS OF ALTERNATIVE TAKEOFF AND LANDING AIDS

Cennerly H. Digges In AGARD Take-off and Landing Jan 1975 18 p. refs (For availability see N75-21219 13-01)

The various aids for reducing takeoff and landing distance are discussed. The launch aids include rocket assist, catapults and powered lift. The landing aids include reversed turbojet thrust, parachutes and wheel brakes. New technology aimed at reducing the weight or increasing the performance of landing aids is indicated. The ways in which stopping distance is affected by varitions in parameters such as lift coefficient, drag coefficient, reversed thrust, landing velocity and runway friction coefficient

N75-21226 Hoyal Aircraft Establishment, Bedford (England) A TECHNIQUE FOR ANALYSING THE LANDING MA-NOEUVRE

R. F. A Keating In AGARD Take-off and Landing Jan 1975 12 p refs (For availability see N75-21219 13-01)

Studies of steep gradient aviation have highlighted the need to find the underlying piloting strategy of landings. A graphic presentation of landing records is put forward which, it is hoped. will assist in the solution to this problem. By expressing the pilot's longitudinal control activity as equivalent speed and climb rate demands, it is possible to plot simultaneously the direraft motion and the control strategy against the performance chart as a reference grid. By suitable choice of axis scaling, the aircraft's response to simple control input traces out simple geometric patterns such as circular arcs. Examples are given of flight data, principally of the HS 125 in normal, steep and two segment approaches. Power margins and target speeds are discussed for these examples

N75-21227* National Aeronautics and Space Administration Area Research Center, Moffett Field, Calif. **STABILITY AND CONTROL HARMONY IN APPHOACH AND** LANDING

Seth B Anderson /n AGARD Take-off and Landing Jan 1975 8 p. refs (For svailability see N75-21219 13-01)

A review of the factors which affect stability and control harmony in approach and landing is made to obtain a clearer understanding of the proper relationship, the trade-offs involved. and to show how limits in stability and control harmony are established for advanced siroraft. Factors which influence stability and control harmony include the longitudinal short period response of the aircraft and the level of several pitch control characteristics including control power, control sensitivity, and control feel. At low stability levels for advanced aircraft, less conventional control techniques such as DLC are needed to improve harmony and some form of stability augmentation must be provided to improve precession of flight path control and reduce pilot work load

N75-21228 National Aeronautical Establishment, Ottawa

THE INFLUENCE OF STOL LONGITUDINAL HANDLING QUALITIES OF PILOTS' OPINIONS

In AGARD Take-off and Landing K-H Doetsch, Jr. 1975 17 p refs (For availability see N75-21219 13-01) (Contract F33615-71-C-1722)

Consideration is given to some of the factors which distinguish the longitudinal handling qualities of STOL aircraft from those of the CTOL class and to the influence of these differences on pilot's opinions. The effects of wind, wind-shear, frim speed, thrust vector inclination, speed coupling, pitch chracteristics and of using different control technique options on flight-path control are discussed briefly. In flight evaluations of variations in some of these parameters provided a basis for assessing their relative importance to the pilot when he was faced with a demanding instrument approach task. Control of pitch proved to be central to the overall flight path control task and the more easily and precisely the pilot could modulate pitch, the more adverse the speed coupling effects he was prepared to tolerate. For the typical unaugmented stability characteristics of the STOL class of aircraft exhibiting small modal separation, the handling qualities were governed by the overall responses to control and disturbance inputs rather than by the location of individual roots of the characteristic equation

N76-21229 Royal Natherlands Aircraft Factories Fokker. Schiphol-Oost

LOW-SPEED STABILITY AND CONTROL CHARACTERIS-TICS OF TRANSPORT AIRCRAFT WITH PARTICULAR REFERENCE TO TAILPLANE DESIGN

E Obert In AGARD Take-off and Landing Jan 1975 16 p (For availability see N75-21219 13-01)

For modern transport aircraft generally emphasis is put on operational flexibility. This means among other things that the ability is required to operate at low take-off and landing speads under a wide range of loading conditions. Consequently the operational envelope of the sircraft covers a large range of lift coefficients and C.G positions. The ensuing requirements for the design of horizontal tail surfaces and elevators are difficult to fulfil. Some of the low-speed tailplane and elevator problems are considered. Particular reference is made to the possibility of tailplane stall. Some related experience obtained in the design and flight testing of the Fokker-VFW F-27 and F-28 is discussed

N75-21230 Vereinigte Flugtechnische Werke-Fokker G.m.b.H., Bremen (West Germany).

SOME LOW SPEED ASPECTS OF THE TWIN-ENGINE SHORT HAUL AIRCRAFT VFW 514

Hartmut Griem, Juergen Barche, Hans J. Beisenherz, and Guanther Krenz In AGARD Take-off and Landing Jan. 1975 19 p refs (For availability see N75-21219 13-01)

The flight characteristics of the VFW 614, short haul aircraft, are discussed. The low speed aspects of the aircraft are analyzed with respect to: (1) wing stall serodynamics, (2) tall stall serodynamics. (3) longitudinal control, and (4) lateral/ directional control. The aircraft design criteria are identified. The dimensions and configurations of the aircraft controls are tabulated. Flight test results are summarized. Author

N76-21231 British Aircraft Corp. Weybridge (England) Commercial Alteraft Div

DIRECT LIFT CONTROL APPLICATIONS TO TRANSPORT AIRCRAFT: A UK VIEWPOINT
M. R. Smith In AGARD Take-off and Landing Jan. 1976

10 p refs (For availability see N75-21219 13-01)

The longitudinal controllability of large conventional transport aircraft during the approach and landing flight phases, and of conventional high lift 'STOL' alreraft during short landings, is discussed. The advantage of a direct lift control system (DLC) is indicated, and a practical design, using wing spoilers, is described, with its disadvantages. Theoretical and flight simulator investigations on the VC.10 sizorsh, and the BAC 1-11 sizoraft are described, together with investigations of similar systems for Improving the automatic landing of current British jet erroraft. Some recent investigations on a DLC application to a STOL stroraft are noted it is concluded that DLC applications can improve controllability and performance for most transport aircraft. A more detailed study is required for each application before its true value can be assessed, even for large transport aircraft Application of DLC to conventional lift STOL aircraft looks attractive for achieving satisfactory flare performance.

N75-21232 Messerschmitt-Boelkow-Blohm G.m.b.H., Munich (West Germany).

INVESTIGATIONS ON DIRECT FORCE CONTROL FOR CCV AIRCRAFT DURING APPROACH AND LANDING

Wolfgang J Kubbat In AGARD Take-off and Landing Jan 1975 11 p (For availability see N75-21219 13-01)

The aerodynamic characteristics of control configured vehicles (CCV) with direct force controls (DFC) are discussed. The following aspects are considered: (1) the influence of the controls on the natural stability, (2) the influence of DFC on the controllability of the aircraft. (3) the integration of the DFC with the control system in CCV designs. (4) the behavior of CCV aircraft with DFC during approach and landing, and (5) the relationship of the results presented in the basic CCV concept

N78-21233 Yingling (George L.), Dayton, Ohio GUIDANCE PHILOSOPHY FOR MILITARY INSTRUMENT LANDING

George L. Yingling In AGARD Take-off and Landing 1975 13 p refs (For availability see N75-21219 13-01)

Instrument landing guidance philosophy for military aircraft is affected by the type of operation, the nature of the environment. the kind of aircraft involved and system dynamics considerations. Guidance philosophy and requirements are inseparable from control dynamics and tradeoffs exist between the two in arriving at an optimum solution for particular cases. In some countries. compatibility and interoperability with the civil system is considered important if not assential. The National Microwave Landing System program in the U.S.A. is of great interest internationally, and the U.S.A. Department of Defense is supporting, at present, the goal of a common civil/military system. Representative unclassified operational requirements are reviewed as a lead to discussing the various factors having an impact on choice of guidence philosophy. The single most important consideration is the choice of technique to overcome landing guidance system multipath effects. The choice of technique must satisfy the many system dynamic considerations and present field test programs must provide clear and valid engineering data upon which to base a decision. A system solution to a hypothetical but representative military situation is presented for discussion purposes. In addition a requirement for an all-airborne, self-contained landing system is discussed.

THE IMPROVEMENT OF VISUAL AIDS FOR APPROACH AND LANDING

A. J. Smith and D. Johnson In AGARD Take-off and Landing Jan. 1975 15 p refs (For availability see N75-21219 13-01)

The effect of fog on the operational capability of runway lights is discussed. A study on the variations of fog gradients with altitude is reported. Improvements in approach and runway lighting to overcome the attenuation caused by fog are described. The characteristics of a precision approach path indicator for steep gradient and two-segment approaches are analyzed. The author states that landings made using the improved equipment have been achieved with a touchdown scatter that is much smaller than is normally achieved

N75-21235 National Aerospace Lab., Amaterdam (Netherlands). FLIGHT TESTS WITH A SIMPLE HEAD-UP DISPLAY USED AS A VISUAL APPROACH AID

G. L. Lamers // AGARD Take-off and Landing Jan. 1975 11 p. refn (For availability see N75-21219 13-01)

A simple head-up display (HUD), giving only glide path information with a depressed horizon bar, has been tested as an approach aid in visual flight conditions. An important improvement was observed in the accuracy of the glide path performance when approaches with the use of a HUD are compared with visual approaches without an approach aid. Using the HUD decreased the standard deviations of height by a factor of 2 to 4 depending on distance from the runway. From this limited series of tests no significant differences in other flight parameters could be demonstrated. The subject pilots indicated a preference for use of the HUD during visual approaches. especially in night conditions. Author

Jean-Claude Wanner In AGARD Take-off and Landing Jan 1975 14 p in FRENCH; ENGLISH summary (For availability see N75-21219 13-01)

A model of pilot behavior during the takeoff and landing phases of flight was constructed. The model was used to determine the necessary cues and in turn the parameters which have to be displayed in order to minimize the pilot work load and improve flight safety. A future cookpit display was designed, based on the display parameters. The main part of the system is a head-up display presenting the ground track of the air velocity vector and the total climb angle. With these two parameters the pilot can directly control the airpath, knowing exactly the necessary rating of the engines and observing a correct safety margin for

N75-21238 Ministry of Transport, Ottawa (Ontario). SOME DHC 6 TWIN OTTER APPROACH AND LANDING EXPERIENCE IN A STOL SYSTEM

Richard P. Bentham In AGARD Take-off and Landing Jan. 1975 11 p (For availability see N75-21219 13-01)

The Canadian Government's decision to introduce a STOL demonstration service revealed a need for practical data and flight experience to assist in aircraft approval and development of safe operational procedures. From 1971 to 1973, a series of flight tests concerned with the steep approach and landing task were carried out, initially in a DHC-5-100 Twin Otter and later in a DHC-8-300S. Approach angles of 6 deg, 7 deg, and 8 deg were assessed in terms of pilot work load and aircraft touchdown and landing distances. Other relevant factors peculiar to the steep approach and landing task were investigated including transition from en-route guidance to approach guidance, crew co-ordination, night operation, missed approach and engine out missed approach, and approach turbulence and wind shear. Community noise sensitivity was closely monitored. The flight test program resulted in some modifications to the production aircraft, the development of approach and landing operating procedures and the definition of some potential problem areas. P. G. Hamel, K. K. Wilhelm, D. H. Hanke, and H. H. Lange. In AGARD Take-off and Landing Jan. 1975 19 p refs (For availability soe N75 21219 13-01)

The trends in aircraft approach and landing procedures are such that increasingly noise abatement constraints impact on vehicle flying (handling) qualities. A ground-based flight simulator program and concurrently a flight test program were conducted using a MBB HFB-320 Hansa Jet airplane which was retrofitted with an analogue fly-by-wire flap and thrust control system. The direct lift control system was used for alleviating handling qualities problems during steep noise-abatement landing approaches. A variable direct lift control system was made feasible for optimization purposes by changing the gearing ratio of the electric flap-elevator interconnect. Facilitation in pilot's workload and improvements in flight path control were analyzed by statistical methods. Experiences gained by flight test results and noise measurements show that routine 2-segment noise-abatement approach paths can be introduced successfully when adequate path guidance, nuick-response flight path corrections and minimum throttle activity are possible.

METHODS FOR AIRCRAFT STATE AND PARAMETER

IDENTIFICATION

May 1975 440 p refs Meeting held at Hampton, Va., 5-8 Nov 1974

(AGARD-CR-172) Avail: NTIS HC \$11.25

Papers which discuss and compare results obtained with different parameter identification techniques applied to specific fighter aircraft at high angles of attack, subsonic, and supersonic transports, VTOL and STOL aircraft, and helicopters are presented Special problems areas such as systems modeling with high internally generated fluctuations, aircraft state estimation in not steady flight, and parameter identification for nonlinear aerodynamic regimes are covered. For individual titles, see N75-29998 through N75-30026.

N75-29998 Royal Aircraft Establishment, Bedford (England). MODELLING OF SYSTEMS WITH A HIGH LEVEL OF INTERNAL FLUCTUATIONS

J. G. Jones In AGARD Methods for Aircraft State and Parameter Identification May 1975 18 p refs (For availability see N75-29997 21-01)

The problem of modelling the structure of systems with a high level of internally generated fluctuations is discussed and problems in parameter identification are reviewed. The systems considered typically have two types of behavior, determined by the magnitude of a controlling parameter which influences stability For a finite range of parameter values the system is stable and its structure may be described by a detestic set of differential equations. If not subjected to external disturbances the system will achieve a state of equilibrium. At some 'critical' value of the parameter, however, the system becomes unstable and beyond this boundary the system no longer achieves a state of equilibrium but may exist (as a result of nonlinearities) in a steady state typified by continuous fluctuations. This state may either be described as a regular limit-cycle type of oscillation or may be essentially random in nature. Practical examples include aircraft buffeting and wing-rocking, forms of fluctuating motion which occur respectively in structural and rigid-body modes. In these examples aircraft incidence may be regarded as the controlling parameter and the fluctuating motion is associated with the existence of extensive areas of separated flow at high incidence A structure which falls into the type considered, is the standard human-pilot model in which the internal fluctuations are represented by a 'remnant'. An example is discussed which illustrates problems that can arise in the identification of this type of system when operating as part of a closed loop. Author

N75-29999 Calapan Corp. Buffalo, N.Y. IDENTIFICATION OF NONLINEAR AERODYNAMIC STABIL ITY AND CONTROL PARAMETERS AT HIGH ANGLE OF

B. J. Eulrich and E. G. Rynaski In AGARD Methods for Alreraft State and Parameter Identification May 1975 15 p refs (For availability see N75-29997 21-01) (Contract F33615-72-C-1248)

A procedure is described for the estimation of the nonlinear aerodynamic stability and control coefficients at high aircraft angles of attack. It is based on a nonlinear, Iterated Kalman filter/fixedpoint smoother identification algorithm and a least squares equation error method. Key ingredients for successful identification are the mathematical model, instrumentation system, control inputs, and the identification algorithm. The major emphasis is placed on the use of the identification procedure in analyzing high angle of attack flight data. Specifically, model form and initial estimates are established from wind tunnel data using series expansions to represent the nondimensional force and moment coefficients for selected ranges of angle of attack. This high dimensional representation is reduced by: (1) preprocessing the flight data using the instrumentation system model and the six-degree-of-freedom aircraft kinematic equations to perform optimal state estimation and hence decrease the effects of instrumentation errors; and (2) separating the six equations of motion into two separate four-degree-of-freedom systems; one for extracting the longitudinal coefficients and the other for the lateral-directional coefficients. Specific problems associated with the identification procedure at high angles of attack and parameter identifiability problems caused by poorly conditioned flight data are reviewed. Selection of the coordinate system for the aircraft model, the determination of the initial covariance estimates, and the measurement and process noise statistics required to use the iterated Kalman technique are discussed Author

METHODS USED FOR OPTIMIZING THE SIMULATION OF CONCORDE SST USING FLIGHT TEST RESULTS

Jacques Tardy In AGARD Methods for Aircraft State and Parameter Identification May 1975 10 p (For availability see N75-29997 21-01)

The elaborate calculation means provided by a simulator were used in the design of CONCORDE. Different simulators of more and more sophistic-sted design, were installed from a fixed base analog simulator to the present simulator which is described. This simulator is used for various design purposes: development studies for the aircraft and its systems, handling qualities, flying controls, various piloting aids, failure research; flight test preparation and crew training, crew work load studies; studies for introducing CONCORDE into air traffic in liaison with EUROCONTROL. and preparation for aircraft certification. examination of requirements and participation in certification for the most critical conditions to be tested in flight, testing very low probability failures or investigations in the extreme regulatory atmospheric conditions

N75-30001* National Aeronautics and Space Administration Langley Research Center, Langley Station, Va. APPLICATION OF A NEW CRITERION FOR MODELING Lawrence W. Taylor, Jr. In AGARD Methods for Aircraft State and Parameter Identification. May 1975.9 p. refs. (For availability see N75-29997.21-01). CSCL. 12B.

A new criterion is proposed for modeling systems which promises to be useful in deciding how complex a model should be. The criterion is based on the expected model response error instead of the error in fitting the data used for estimating the model parameters. The new criterion also does not require withholding data to be used exclusively for testing. There remains, however, the difficulty of testing a large number of candidate models that correspond to the combinations of terms used in the dynamic equations. A computational approach is suggested which greatly reduces the computations required in searching for the best model. In the suggested approach the gradient of the response with respect to the model coefficients is held fixed and numerous combinations of terms are assessed. After determining the most promising candidate model, the gradient is updated and the process is repeated. This procedure gives greater assurance that the best model is selected and does not rely on the analyst's judgement.

N75-30002* National Aeronautics and Space Administration. Langley Research Center, Langley Station, Vs. A MONTE CARLO ANALYSIS OF THE EFFECTS OF

A MONTE CARLO ANALYSIS OF THE EFFECTS OF INTRUMENTATION ERRORS ON AIRCRAFT PARAMETER IDENTIFICATION

Wayne H. Bryant and Ward F. Hodge In AGARD Methods for Aircraft State and Parameter Identification May 1975 19 prefs (For availability see N75-29997 21-01) CSCL 01C

An output error estimation algorithm was used to evaluate the effects of both static and dynamic instrumentation errors on the estimation of aircraft stability and control parameters. A Monte Carlo analysis, using simulated cruise flight data, was performed for a high performance military aircraft, a large commercial transport, and a small general aviation aircraft. The effects of variations in the information content of the flight data, resulting from two different choices of control input maneuvers, were also determined. The results indicate that unmodeled instruments. tion errors can cause inaccuracies in the estimated parameters which are comparable to their nominal values. Control Input errors and angular accelerometer lags were found to be most significant of the instrumentation errors evaluated, and the perturbations they produce are much larger than those arising from the combined effects of static errors and white noise in the output response measurements Author

ADVANCED FLIGHT TEST INSTRUMENTATION: DESIGN
AND CALIBRATION

R. J. A. W. Hosman In AGARD Methods for Aircraft State and Parameter Identification May 1975-17 p. refs (For availability see N75-29997-21-01)

A series of flight tests with a Hawker Hunter Mk.7 aircraft was performed to determine the performance as well as stability and control characteristics. The instrumentation system used in these tests is described. Major topics discussed include: the choice of the specifications for the transducers as related to the desired accuracy of the characteristics of the aircraft to be determined; the methods applied to meet these specifications, especially for the pressure transducers; the calibration program to determine the characteristics of the transducers in the statistical format, and to apply modern system theory to the analysis of the flight measurements.

A COMPLEMENTARY FILTERING TECHNIQUE FOR DERIVING AIRCRAFT VELOCITY AND POSITION INFORMATION

Frank R. Niessen In AGARD Methods for Aircraft State and Parameter Identification May 1975 16 p refs (For availability see N75-29997 21-01) CSCL 01C

An onboard navigation system which employed complementary filtering was developed to provide velocity and position information. The inputs to the mix filter included both acceleration inputs, which provided high-frequency position and velocity information, and rader position inputs, which provided the low-frequency position and velocity information. Onboard arcraft instrumentation, including attitude reference gyros and body-mounted accelerometers, was used to provide the acceleration information. An in-flight comparison of signal quality and accuracy showed good agreement between the complementary filtering system and an aided inertial navigation system. Furthermore, the complementary filtering system was proven to be satisfactory in control and display system applications for both automatic and pilot-in-the-loop instrument approaches and landings.

DESIGN AND EVALUATION OF A SYMMETRIC FLIGHTTEST MANOEUVRE FOR THE ESTIMATION OF LONGITUDINAL PERFORMANCE AND STABILITY AND CONTROL
CHARACTERISTICS

H. W. Kleingeld In AGARD Methods for Alteraft State and Parameter Identification May 1975 6 p refs (For availability see N75-29997 21-01)

Longitudinal performance and stability and control data are derived from measurements in one flight test maneuver. The maneuver is comprised of quasi-steady accelerating parts and nonsteady oscillating parts. A moving base simulator is used to determine the problems which accompany the manual application of the required elevator control input and to teach the pilot to generate the signal without feedback. Results of this evaluation program are given and compared with corresponding results of the actual flight tests.

DETERMINATION OF STABILITY DERIVATIVES FROM FLIGHT TEST RESULTS COMPARISON OF FIVE ANALYTICAL TECHNIQUES

Horst Wuemenberg, Heinz Friedrich, Ulrich VonMeler, and Hans-Joachim Munser. In AGARD Methods for Aircraft State and Parameter identification May 1975. 12 p. refs (For availability see N75-29997. 21-01).

Analytical techniques in stability derivatives estimation are compared. The test alicraft, a G 91-T3, was equipped with a sophisticated instrumentation and data acquisition system. The analytical techniques, manual evaluation of special flight maneuvers, time vector method, forced oscillation method, analog matching, and regression analysis are compared in relation to the amount of time and equipment for the flight testing, complication of the data reduction, and the quality of the results. The accuracy of the data acquisition is the most important problem. Therefore an accurate check of all test data has to be performed before sophisticated evaluation programs are used. It is summarized that several measuring and evaluation techniques should be used in parallel.

N75-30008 Office National d'Etudes et de Recherches Aerospatiales, Paris (France).

FIVE IDENTIFICATION METHODS APPLIED TO FLIGHT TEST DATA

Jaan-Pierre Chaquin In AGARU Methods for Aircraft State and Parameter Identification May 1975 8 p. refs (For availability see N75-29997 21-01)

The parameter of linear multivariable systems using input and output measurements is determined. It is assumed that the physical system, which is to be investigated, can be described by a sot of linear differential equations with constant coefficients. These estimations are to be applied to the derivation of active control parameters. Tests of well known methods, such as least squares, modulating functions, conjugate gradients and analog matching, are developed. Some results are proposed to be used as support for the comparison of the comparison of the different methods.

N75-30000° Harvard Univ., Cambridge, Mass. STATUS OF INPUT DESIGN FOR AIRCRAFT PARAMETER IDENTIFICATION

R. K. Mehra and N. K. Eupta (Systems Control, Inc.) In AGARD Methods for Aircraft State and Parameter Identification May 1975 21 p. refs (For availability see N75-29897 21-01) (Contracts NAS4-2068; NO0014-67-A-0298-0008) CSCL 01C

Results are presented on the design of aircraft inputs (i.e. elevator, rudder and seleron deflection time histories) to identify aircraft stability and control derivatives from flight test data. The problem is first reduced to an optimization problem with differential and integral constraints. The criteria used are either expressed in terms of the Cramer-Rao lower bound on the covariance matrix of the parameter estimates or in terms of the maximum prediction error variance. Both time-domain longitudinul and lateral dynamics of C-8 and Jet Star aircrafts and comparison with doublet type inputs are made.

ADVANCEMENT IN PARAMENTER IDENTIFICATION AND AIRCRAFT FLIGHT TESTING

Roger A. Burton In AGARD Methods for Aircraft State and Parameter Identification May 1975 16 p refs (For availability see N75-29997 21-01)

Results are presented from a program to develop parameter identification technology with specific emphasis placed on studies conducted in parameter identifiability and (optimal) control inputs for parameter estimation. Nevy applications for parameter identification technology are discussed with specific areas in aircraft stability and control testing outlined. Specific criteria required for defining optimal control inputs and establishing

parameter identifiability are discussed. Parameter identification results from the analysis of flight test data are presented which establish the need for considering input design in planning tests for extracting aerodynamic coefficients from flight test data. Parameter identifiability results for specific control inputs used are presented. In cases where identifiability problems are shown to exist the use of a rank deficient solution to improve parameter identifiability to demonstrated.

PRACTICAL ASPECTS OF USING A MAXIMUM LIKELI-HOOD ESTIMATOR

Kernoth W liff and Richard E. Maine. In AGARD. Methods for Aircraft State and Parameter Identification. May 1975. 15 p. refs. (For availability see N75-29997. 21-01). CSCL 01C.

The application of a maximum likelihood estimator to flight data is discussed and procedures to facilitate routine analysis of a large amount of flight data are proposed. Flight data were used to demonstrate the proposed procedures. Modeling considerations are discussed for the system to be identified, including linear aerodynamics, instrumentation, and data time shifts, and serodynamic blases for the specific types of maneuvers to be analyzed. Data editing to eliminate common data acquisition problems, and a method of identifying other problems are considered. The need for careful selection of the maneuver or portions of the maneuver to be analyzed is pointed out. Uncertaintly levels (analogous to Cramer-Rao bounds) are discussed as a way of teoognizing significant new information.

DETERMINATION OF AIRCRAFT DERIVATIVES BY AUTOMATIC PARAMETER ADJUSTMENT AND FREQUEN-CY RESPONSE METHODS

M. Merchand and R. Koehler In AGARD Methods for Aircraft State and Parameter Identification May 1975 18 p refs (For availability see N75-29997 21-01)

Experiences are reviewed in the estimation of alicraft parameters by means of three identification methods frequency response, maximum-likelihood, and model with automatic parameter adjustment Results using flight test data from the Do-27 and HFB-320 attracts are presented. The effects of including nonlinear terms and turbulence in the model are also discussed. The model with the automatic parameter adjustment method was used for studying the problems of derivative identification for rotorcraft type vehicles. Proliminary results obtained when evaluating simulated Sikorsky S-61 (light data with various input signals are given. Some aspects of designing input signals for flight tests are discussed, system parameters and are easily flowby the pilot.

N75-30015 Air Force Flight Test Center. Edwards AFB. Calif A COMPARISON AND EVALUATION OF TWO METHODS OF EXTRACTING STABILITY DERIVATIVES FROM FLIGHT TEST DATA

Paul W. Kusten In AGARD Methods for Aircraft State and Paremoter Identification May 1975 26 p refs (For availability see N75-29997 21-01)

Two methods for extracting stability derivatives from flight data are compared A modified Newton-Raphson minimization technique and a digital analog (hybrid) matching technique were used to analyze the same data maneuvers obtained from two aircraft. About 55 maneuvers of an F 111E sircraft were analyzed over a Mach 0.3 to 2.0 and an engle of attack range of 3 to 19 degrees. About 15 maneuvers were analyzed for the X-24A. lifting body at Mach numbers of 0.8 and 0.9 and an angle of attack range of 4 to 1.3 degrees. Stability derivatives were extracted from these maneuvers, and the results from the two techniques along with wind tunnel results were compared. The hybrid matching mathematical model contained complete five-degree-of-freedom equations (no velocity derivatives) with variable dynamic pressure, whereas the Newton-Raphson model used uncoupled, three-degree-of-freedom equations with constant dynamic pressure. Both techniques were found to be capable of giving accurate results, but required a fairly extensive knowledge of the method being used. The Newton-Raphson technique tends to be less time consuming, and is suited for processing large quantities of data maneuvers. Hybrid matching is well suited for programs in which a limited amount of data is processed for Author

MODEL STRUCTURE DETERMINATION AND PARAMETER
IDENTIFICATION FOR NONLINEAR AERODYNAMIC
FLIGHT REGIMES

M. Earl Hall, Jr. Narendra K. Gupta, and James S. Tyler, Jr. In AGARD Methods for Aircraft State and Parameter Identification May 1975 21 p. refs (For availability see N75-28997 21-01) (Contract N00014-72-C-0328)

The identification of nonlinear stall/spin regime air dynamic forces and moments is discussed, along with applications to simulated and flight test response data. For this development, a two-stop method is presented. The first step is the application of an algorithm which determines the order and coefficients of polynomial expansions which determines the order and coefficients of polynomial expansions which determines the order and coefficients of polynomial expansions of the nonlinear serodynamic forces and moments which characterize the stall/post-stall flight regime. The second step is the use of a nonlinear six degree-of freedom maximum likelihood algorithm which accurately estimates the values of the polynomial coefficients. This method was applied to simulated and flight test data for a twin engine swept wing fighter aircraft. Suggested approaches to general nonlinear flight regime identification are given.

N76-30019° National Aeronautics and Space Administration. Langley Research Center, Langley Station, Va. IMPORTANCE OF HELICOPTER DYNAMICS TO THE MATHEMATICAL MODEL OF THE HELICOPTER William F. White, Jr. In AGARD Methods for Aircraft State and Parameter Identification May 1975 12 p refs Prepared by Army Air Mobility Res. and Develop. Lab., Hampton, Va. [For availability see N75-29997 21-01]

CSCL 01C A mathematical model of the helicoptur requires appropriste representation of the constituent elements of rotor dynamics. General-purpose programs that model a variety of configurations for a broad range of operating conditions result in varying and incompatible levels of sophistication. Analysis of specific dynamic problems facilitates the identification of configuration parameters which determine system behavior. For the present analysis, the nonlinear equations of a torsionally rigid hingeless rotor are linearized about an equilibrium condition to determine flap-lag stability characteristics in hover. A collocation method was used to obtain the coupled natural frequencies and modes. These modes allow exact treatment of the effect of elastic coupling which more than compensates for the destabilizing inertial coupling. The sensitivity of damping to the number of modes was found to be small, and reasonable accuracy was obtained the first flapwise and edgewise coupled modes. The range of destabilizing precone was found to be small

ESTIMATES OF THE STABILITY DERIVATIVES OF A HELICOPTER AND A V/STOL AIRCRAFT FROM FLIGHT DATA

D. G. Grould and W. S. Hindson. In AGARD. Method for Alicraft State and Parameter Identification. Jul. 1957. 9 p. refs (For availability see N75-29997 21-01)

Stability derivatives for the Bell 205 helicopter were derived from flight data using a least squares gussi-linearization technique. The aircraft model, which included a first order representation of rotor response characteristics, was based on fundamental parameters descriptive of the particular design. A conglome-se analysis procedure estimates based on data from several similar maneuvers was used to increase the confidence in the results observed. Data from CL-84 V/STOL sircraft were also analyzed, indicating the velidity of certain a priori longitudinal stability derivatives for the aircraft, and yielding estimates of others. The results indicate the need to use a more elaborate modeling technique, (such as was used for the Bell 205) which takes into account the particular complexities of the aircraft. Author

John A. Molusis In AGARD Methods for Aircraft State and Parameter Identification May 1975 31 p refs Sponsored in part by NASA and USAAMRDL (For availability see N75-29997 21-01) CSCL 01C

A general procedure is presented for systematic development of rotorcraff models for use in systems identification, which includes fuselage and rotor degrees of freedom (DOF). Formula tions for rigid blade flap and lag as well as the normal mode representation of an elastic blade are developed for hingeless and articulated rotor systems. The method of multiblade coordinates is used to obtain linear constant coefficient state variable models of various levels of approximation. Two of the approximate models, a 6 DOF, are identified from a nonlinear articulated helicopter computer simulation. The results demonstrate the accuracy attainable for each model. Advanced results outline the status of rotorcraft modeling and systems identification and indicate areas that require further investigation.

A prerequisite in the use of response-feedback variable stability aircraft to obtain flying qualities data is an accurate method for estimating stability and control parameters from flight data. It is necessary, however, that such methods be efficient and cost effective to minimize the effort and expense spent performing the estimation. The application of a digital identification technique X-22A V/STOL research aircraft is discussed. Emphasis is placed on practical aspects of identifying efficiently data covering a wide range of dynamic characteristics, particular attention is paid to the elimination of adjustments in the technique for each data run and the use of particular pilot control inputs to maximize identifiability. Results are presented for a variety of simulated dynamics.

Rodney C. Wingrove In AGARD Methods for Aircraft State and Parameter Identification May 1975 10 p. refs (For availability see N75-29997 21-01) CSCL 01C

Longitudinal aerodynamic coefficients are estimated from data recorded during flight tests of a powered-lift STOL aircraft. A comparison is made between the coefficient values determined by the regression and quasilinearization identification techniques from records taken during elevator pulse maneuvers. The results show that for these tests the regression method provides less scatter in coefficient estimates and provides better correlation with the predicted values. Special techniques are developed which allow identification of the coefficients from records taken during landing maneuvers in which the aircraft encounters turbulence while-flying in ground effect. Flight test results are presented to illustrate the effects of air turbulence and ground proximity on the estimated coefficient values.

ESTIMATION OF ELASTIC AIRCRAFT AERODYNAMIC PARAMETERS

Robert C. Schwanz and William R. Wells In AGARD Methods for Aircraft State and Parameter Identification May 1975 10 p refs (For availability see N75-2997 21-01)

The Importance of Including sercelesticity in sircraft parameter estimation is discussed using the B52E and C-5A sircraft as examples. A parameter estimation method, employing the modal truncation dynamics math model and the maximum likelihood estimation algorithm, is selected to illustrate the computational difficulties that must be solved. A combined in-house and contractual research program is then cutlined that addresses these anticipated problem areas. The alreraft selected for the initial application of the methods is the B52E that was flown in the Control Configured Vehicle (CCV) research program of the Af Flight Dynamics Laboratory.

The possible definitions are examined of the term control configured vehicle (CCV) and some other associated notions such a autostabilization, flight by wire, etc. The characteristics common to all the so called CCV systems are examined simultaneously, together with the most noteworthy differences encountered. The present possibilities of these systems are reviewed, considering, for each case, the safety objectives, and performance objectives for transport and combat aircraft. Finally, long term, prospects are considered.

N78-30029 Royal Aircraft Establishment, Bedford (England) ACTIVE CONTROL AS AN INTEGRAL TOOL IN ADVANCED AIRCRAFT DESIGN

W. J. G. Pinsker. In AGARD. Impact of Active Control Technol on Airplane Design. Jun. 1975. 12 p. refs (For availability sen. N75-30027-21-01)

The scope of active control in the design and operation of aircraft is broadly reviewed, and the automatic control, stability and control augmentation, artificial static stability, gust alleviation, stall and spin protection and various methods for reducing sirframe loads are studied it is argued that active control should not be treated as a piece-meal solution to isolated design problems but rather refinements will the true potential of these powerful techniques be realized in particular it is shown that many CCV applications require commensurate improvement in the serodynamic performance of the control surface.

TRANSPORT AIRCRAFT WITH RELAXED/NEGATIVE LONGITUDINAL STABILITY RESULTS OF A DESIGN STUDY

Heinz G. Kiug. In AGARD impact of Active Control Technol on Airplane Design. Jun. 1975. 15 p. (For availability see N75-30027-21-01).

Application of active longitudinal control on transport ancraft with relaxed/negative longitudinal stability was studied. Using two aircraft of different configuration as basising designs versions incorporating active longitudinal control were derived Configuration changes were studied with varying tail size, and center of gravity position. Based upon the requirement for handling qualities equivalent to the baseline designs, optimum control laws were derived. Controllability and stability were checked by simulating various gust cases. Limits for tail size and og-position were derived. Wing size was changed where required to hold performance unchanged. Structural and fuel weight changes were calculated and the configuration, within the geometrical and controllability limits, giving the highest payload increase, was selected. Sensitivity of payload benefit to performance specification was checked by parametric variations, it was found that payload benefit depends upon configuration to a high degree. Best payload benefit will be achieved for high wing. T-tail STOL aircraft using large trailing edge flaps. Payload increase may be up to 15%

IMPACT OF ACTIVE CONTROL TECHNOLOGY ON AIR-CRAFT DESIGN

P. R. G. Williams and B. S. Campion In AGARD Impact of Active Control Technol on Airplane Design Jun. 1975 6 p (For availability see N75-30027 21-01)

Use of active control technology on civil transport aircraft is considered, both as regards improvement of a conventional aircraft and as regards development of new configurations to exploit such technology. Significant gains in weight and operating cost may be made by using artificial stability augmentation and load alleviation on a conventional design, though the precise gains depend on the way in which weight savings are exploited. Unconventional means are suggested whereby active control technology might best be exploited on short and long range subsonic alroraft, and also on supersonic aircraft, it appears that is largest gains are likely to be made when new techniques are used in combination rather than singly.

ACTIVE CONTROL TECHNOLOGY: A MILITARY AIRCRAFT
DESIGNER'S VIEWPOINT

R. Melling In AGARD impact of Active Control Technol on Airplane Design Jun. 1975 15 p (For availability see N75-30027 21-01)

The most likely gains to be obtained by the application of active control technology to small combat aircraft are considered. There are seen to be considerable attractions, although the most significant benefits may turn out to be orientated towards the improved control and design freedom offered by ACT rather than towards revolutionary shapes or greatly increased efficiency or reduced weight. In the design of the ACS itself, it is considered essential that a mechanical back up is avoided in order to produce a more flexible, efficient and safe system, and to this end a suitably progressive system design philosophy must be developed. Despite some doubts as to the more ambitious claims for ACT, its ultimate adoption is expected for all but the simplest of aircraft.

N78-30035 National Aerospace Lab., Amsterdam (Netherlands), HANDLING QUALITY CRITERIA DEVELOPMENT FOR TRANSPORT AIRCRAFT WITH FLY-BY-WIRE PRIMARY FLIGHT CONTROL SYSTEMS

H. A. Mooij. In AGARD. Impact of Active Control Technol. on Airplane. Design. Jun. 1975. 14 p. refs. (For availability see N75-30027-21-01).

The introduction of fly-by-wire primary flight control systems in future transport aircraft, in some cases including direct-lift-control, makes it highly desirable to initiate further studies into handling quality criteria for future guidence in system design. The handling quality criteria for such aircraft must be based on parameters which describe the combination of the aircraft and its closed loop flight control system. Approach flight simulation and compensatory tracking, performed on a three degrees of freedom flight simulator as applied to a conceptual jet fransport developed around the relaxed static stability concept, is described. The stiffness of the pitch attitude system and the effectiveness of the direct-lift-control-system were varied. The following topics are discussed required direct-lift-control-effectiveness for an

The state of the s

aircreft with a very low value of the normal acceleration sensitivity, required bondwidth of the pitch attitude control system for an aircreft with a value of the normal acceleration sensitivity typical for the present-day jumbo aircraft, pilot opinion on the absence of a stable stick force/(deflection) versus alrapeed gradient for pitch-stabilized aircraft, results of compensatory tracking experiments, and evaluation of the applicability of the criterion for the configurations tested.

CONTROL OF AN ELASTIC AIRCRAFT USING OPTIMAL CONTROL LAWS

Werner Dressler /n AGARD Impact of Active Control Technol. on Airplane Design Jun. 1975 11 p (For availability see N75-S0027 21-01)

The design of a multivariable control system for gust alleviation is demonstrated. The use of computers for control designs, summarized under the name computer stood design is described. The gust control system for gust alleviation is integrated into an overall flight guidance control system. Two control designs, using optimal control laws, are achieved, one with complete and the second with incomplete state measurement. In the model description the elastic behavior of the wing is included as well as the nonsteady serodynamic lift generation and the dynamic behavior of the actuators. For a STOL-transport aircraft the efficiency of gust alleviation are shown in a flight through turbulent air. The increase of wing lifetime and the corresponding decrease in structure weight by use of a gust alleviation system is calculated.

N75-30037 Office National d'Etudes et de Racherches Aerospatiales, Paris (France). CLOSED FORM EXPRESSION OF THE OPTIMAL CONTROL OF A RIGID AIRPLANE TO TURBULENCE

Gabriel Coupry In AGARD Impact of Active Control Technol on Airplane Design Jun. 1975 10 p. refs. In FRENCH; ENGLISH summary (For availability see N75-30027 21-01)

The flight of military aircraft at high speed, low altitude makes it necessery to use ride control systems to improve comfort, handling qualities and combat ability. The open loop system that is described senses turbulence which is used, after flittering, to set on the controls. Such a system does not change at all the handling qualities of the aircraft. Wiener's theory is used to derive in closed form the transfer function of the filter used for control it is shown that this transfer function can be expressed in autoadaptative form, the poles being proportional to the velocity of the aircraft. The Influence of parameters like mass, scale of turbulence, is discussed.

APPLICATION OF ADVANCED MODEL-FOLLOWING TECHNIQUES TO THE DESIGN OF FLIGHT CONTROL SYSTEMS FOR CONTROL CONFIGURED VEHICLES

Gerd Hirzinger In AGARD Impact of Active Control Technol on Airplane Design Jun 1975 15 p refs (For availability see N75-30027 21-01)

After a review of optimal control, the model-following concept is applied for approaching a deared tracking behavior, especially concerning the airplane's response to a flight path angle command, in a systematic way. However, it turns out that the disturbance behavior of the controlled system, represented by the airplanes response to an initial deviation in the flight path angle, is unsatisfactory. Therefore a new concept combining model following and partial state vector freedback is applied for designing disturbance behavior and tracking behavior separately, in each of both cases achieving a good compromise between the desired system trajectory and limited control action. It appears that the control system thus designed is very insonative to variations in the most critical parameter, that is the location of the center of gravity.

F. M. Krachmalnick, R. L. Berger (AFFDL), J. E. Hijnter, J. W. Morris (AFFDL), and J. K. Ramage (AFFDL). In AGARD Impact of Active Control Technol on Airplano Design. Jun. 1976. 24 p. (For availability see N75-30027-21-01).

The major portion of the Survivable Flight Control System (SFCS) Program initiated by the United States Air Force in July 1969 was performed to establish the practicality of active control concepts for use in future military aircraft. The SECS quadruplex (four channel redundancy) primary flight control system is described incorporation of this type of control system in a tactical vehicle is expected to provide benefits in enhanced survivability, reliability, maintainability, cost of ownership, aircraft design freedom, and aircraft maneuvering performance. The simulations and ground-based system compatibility testing performed to verify equipment performance and establish high level of pilot confidence prior to flight, are discussed. A summary of the flight test results obtained during 84 successful flights is presented. Flight test results indicate that the F-4 with the SFCS installed exhibits greatly improved handling qualities over those characteristic of the production F-4. This aircraft incorporating control configured vahicle and maneuver load control conceptual features was successfully test-flown and evaluated Results obtained from the pilot-in-the-loop simulations and actual flight tests are discussed. Flight test results verify that significant performance improvements in combat maneuvering envelope. buffer levels, and specific excess power are achievable in the F-4 with judicious application of control configured vehicle

A QUADRUREDUNDANT DIGITAL FLIGHT CONTROL SYSTEM FOR CCV APPLICATION

Wolfgang J. Kubbat /n AGARD Impact of Active Control Technol. on Airplane Design Jun 1975 9 p (For availability see N75-30027 21-01)

A parallel redundant digital fly-by-wire system is described, it will be tested in the neer future on a CCV-test sirroraft (modified F-104 G) Starting from a fall-op, the reasons for the choice of a digital system are outlined. The system works with freely programmable identical sirborns computers which run identical software. The computers perform the control laws and act also as central voters and monitors. Basic of the design is the principle of majority decision with elimination of a failed component. Finally the Quadruplex system represents a functional integration of autopilot, stabilization, air data computation and built-in-test-oquipment.

N76-30043 Naval Air Davelopment Centar, Warminster, Pa. THE ASSET (ADVANCED SKEWED SENSORY ELECTRONIC TRIAD) PROGRAM

C. R. Abrams and W. D. Weinstein (Grumman Aerospace Corp.) in AGARD. Impact of Active Control Technol. on Airplane Design Jun. 1975. 12 p. refs (For availability see: N75-30027, 21-01).

A redundant arrangement of angular rate sensors with skewed input axes, dispersed on an aircraft bulkhead, was designed for fly-by-wire control applications. Compared to other redundant configurations, it best satisfied system reliability, survivability, and maintenance requirements. By also utilizing a high reliability solid-state angular rate sensor, expected maintenance costs will be decreased. The data management system designed for the ASSET configuration featured a parallel path failure detection and isolation algorithm. A unique method of selecting failure thresholds was developed to insure that false alarm probability and system errors were minimized. The results of this effort will contribute to the practical implementation of a digital fly-by-wire system, since a successful attempt was made to match proposed operational requirements. The ASSET concept will therefore provide a fail-operational and combat-survivable set of rate sensors designed to interface with all active control systems, regardless of redundancy requirements.

DESIGN OF AN ENTIRELY ELECTRICAL FLYING CONTROL

G Brohanne, R Deque, and M. Bossard. In AGARD Impact of Active Control Technol on Airplane Design. Jun. 1975. 13 p. (For availability see N75-30027. 21-01).

After reviewing the reasons for using entirely electrical flying controls, that is controls without mechanical stendby systems, and defining the control modes available for a transport alicraft, the general architecture of the system is described. It is shown that if safety requirements impose minimum redundancy, several precautions must be taken for the theoretical reliability achieved by this redundancy to be real. The equipment required is described briefly. From a maintenance point of view, the complexity of the system is compared with that of the flying controls on existing aircraft.

N78-30049° National Aeronautics and Space Administration. Flight Research Center, Edwards, Calif. P-8 DIGITAL FLY-BY-WIRE FLIGHT TEST RESULTS VIEWED FROM AN ACTIVE CONTROLS PERSPECTIVE

Kenneth J. Zelai and Dwain A Deets. In AGARD. Impact of Active Control Technol on Airplane Design. Jun. 1975. 14 p. refs. (For availability see: N75-30027, 21-01).

The results of the NASA F-B digital fly-by-wire flight test program are presented, along with the implications for active controls applications. The closed loop performance of the digital control system agreed well with the sampled-date system design predictions. The digital fly-by-wire mechanization also met pilot flying qualities requirements. The advantages of mechanizing the control laws in software became apparent during the flight program and were realized without secrificing overall system reliability. This required strict software management. The F-B flight test results are shown to be encouraging in light of the requirements that must be met by control systems for flight-critical active controls applications.

N78-30080 Boeing Commercial Airplane Co., Seattle, Wash USE OF ACTIVE CONTROL TECHNOLOGY TO IMPROVE RIDE QUALITIES OF LARGE TRANSPORT AIRCRAFT

Gerald C. Cohen and Richard L. Schoenman. In AGARD. Impact of Active Control Technol. on Airplane Design. Jun. 1975. 16 p. refs. (For availability see N75-30027-21-01)

The analyses, construction, and flight testing of two systems, Beta-vane, and model suppression augmentation system (MSAS), which were developed to suppress gust induced lateral accelerations of large aircraft are described. The Boeing 747 transport was used as the test vehicle. The purpose of the Beta-vane system is to reduce acceleration levels at the dutch roll frequency whereas the function of the MSAS system is to reduce accelerations due to flexible body motions caused by turbulence. Data from flight test, with both systems engaged, shows a 50-70 percent reduction in lateral aft body acceleration levels It is suggested that present day techniques used for developing dynamic equations of motion in the flexible mode region are limited. These techniques produce results which are satisfactory. for analyzing dynamic loads and stability problems, but may be insufficient for development of active control systems operating in the same frequency region Author

N75-30051 Lookheed-Georgia Co., Marietta.
THE C-BA ACTIVE LIFT DISTRIBUTION CONTROL SYS-

William F Grosser, Wayne W Hollenbeck, and Don C Eckholdt In AGARD Impact of Active Control Technol, on Airplane Design Jun. 1971 18 p. refs (For availability see N75-30027 21-01)

The technical details are presented of the development of the Active Lift Distribution Control System (ALDCS) for the C-5A aircraft. A structural loads, and flutter-control system interaction are developed in such a way that the unique aspects of the analysis, aeroelestic wind tunnel test, and flight test portion are bound together to indicate the system design characteristics performance. The purpose of the ALDCS is to reduce gust and maneuver incremental wing root banding moments while minimizing the effects of the control system on torsion, flutter. and flying qualities. These criteria are based on axial load reduction as a means of improving wing fatigue endurance without significantly affecting existing flutter margins or handling qualities. Even though this is a retrofit system which was required to use as much existing hardware as possible, throughout the flight test all design goals were met. The system is currently planned to be many stured and installed on the fleet during the next several years.

THE USE OF HELICOPTER CAPABILITIES IN EAD
WEATHER MEEDS AND REQUIREMENTS FOR FUTURE
EQUIPMENT

K. W. Ernst In AGARD The Guidence and Control of V/STOL Alroraft and Helicopters at Night and in Poor Visibility May 1975 8 p (For availability see N75-30052 21-01)

The operational requirements and problems for improving the use of helicopters in bad weather conditions are discussed. The characteristics for the wide spectrum of applications are given along with flight profiles for bad weather. F.O.S.

N78-30064 Army Operational Test and Evaluation Agency, Fort Belvoir, Va.
TRADEOFFS BETWEEN CREW TRAINING AND EXOTIC EQUIPMENT FOR NIGHT AND FOUL WEATHER FLYING

Elmer R. Ochs. In AGARD. The Guidance and Control of V/STOL Aircraft, and Helicopters at Night and in Poor Visibility. May 1975. 2 p (For availability see N75-30052 21-01).

The requirement for an all-weather, night flying capability is discussed. The solution to achieving this capability is some combination of man-machine capability. A combination which must be reasonably attainable and which represents the best balance between the benefits and burdens associated with both the man and the machine. If the focus is weighted toward the man portion of the equation in order to reduce the machine cost and maintenance burdens, the risk is faced of creating an unacceptable training burden. If the focus shifts too far toward the machine solution, the converse overburden may result. A first step in attacking the problem is to determine the boundaries. The outer boundary is represented by the state of the art while the inner boundary is a full appreciation of what can be accomplished with current assets. A clear understanding of this inner boundary or base line is necessary to objectively assess the additional man-machine requirements which will provide a viable night, foul weather flying capability.

EFFECT ON NAP-OF-THE-EARTH REQUIREMENTS ON AIRCREW PERFORMANCE DURING NIGHT ATTACK HELICOPTER OPERATIONS

In AGARD. The Guidence and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975 10 p refs (For availability see N75-30052 21-01)

Night nap-of-the-earth (NOE) flight is described as it relates to three major areas: man, machine, and operational use. The findings and operational experience reported were encountered in exploratory efforts for a major field experiment. Activities discussed include aviator selection and training, psychological and physiological effects, mission planning, map reading and terrain interpretation, aircraft handling, emergency procedures, and man-machine operations. Behavioral research requirements and other needs established for night NOE training and operations by current scout and attack helicopters are presented, and a training program for night NOE training is offered as a general

H-63 NIGHT OPERATIONS

Richard L. Mills In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975 8 p refs (For availability see N78-30052 21-01)

The H-53 Night Operation System (NOS) includes night vision equipment and an approach and hover coupler. The automatic approach and hover coupler subsystem permits the pilot to transition automatically over all types of terrain, including mountains, from search aititude and cruise speed to a hover and automatically maintain the hover. The night vision equipment extends this depablility to night flights. The basic system was declared operational by the United States Air Force following a ninety-day combat evaluation in Southeast Asia. It is also used by foreign military. Extensive flight testing and operational use have led to additional development tests to further the capabilities of NGS. Flight test results of a prototype symbology generator and prototype electronic localities muter hover coupler are discussed along with the night visior a paper and the approach and hover coupler.

UE ARMY EXPERIENCE IN LOW-LEVEL NIGHT FLIGHT

Robert W. Bauer In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975 6 p. refs (For availability see N75-30052 21-03)

During the period of U.S. conflict in Southeast Asia there were a number of air operations conducted under adverse visibility conditions or at night. There were even a few night operations involving large numbers of aircraft, but most were made up of one or two aircraft, engaged in an insertion, extraction, long-range patrol or supply movement. Some lessons learned from these experiences are reviewed. Current developments and testing have demonstrated an improved capability in night flight, using either selected specialists without night vision systems or a wider group of aviators aided by the night vision goggles. The electroluminescent formation flight lights and rotor-tip lights have greatly increased safety in formation flights at night. But each approach has been hampered by design limitations in display panels, poor lighting quality and poor lighting control in the aircrew stations. Landing in dark unimproved areas, navigation over unfamiliar terrain and target acquisition also present special problems which have not yet been completely overcome. Author

REQUIREMENTS FOR OPERATION OF LIGHT HELICOP-TERS AT NIGHT AND IN POOR VISIBILITY

M. Rade In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility

1975 12 p refs (For evellability see N75-30082 21-01)
Normally the VTOL-ability of helicopters is not used under instrument Flight Rules. For helicopter missions at night and in pour visibility special devices are necessary, but there are only some experimental systems partly derived from devices for fixed wing sirgraft. Basic requirements for normal missions will be defined. They include handling qualities, navigation equipment and landing sids. The use of sensors giving high definition pictures of the terrain in nonvisual conditions are considered. Secondary requirements are generated by some problems resulting from the full use of the all weather capability. They consist of the concept of automatic flight-control-systems and displayarrangements for the pilot. These additional requirements depend on the planned missions and on the possibilities, which are given by the type of helicopter As important conditions for special missions delcing, noise reduction, infrared and radar camouflage will be discussed

N76-30059 Royal Aircraft Establishment, Farnborough (England). HELICOPTER AVIONICS: UK RESEARCH PROGRAMME

H. B. Johnson In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility 1975 7 p refs (For availability see N75-30052 21-01)

A limited review of the status of UK avionic systems for helicopters is given and the current needs of military helicopters discussed. The rapidity with which the use of helicopters has grown is such that it is no longer possible to meet these needs by simple modification of off the shelf equipment A program of research and development work specifically directed towards the needs of helicopters is outlined. This program is centered around the use of a Sea King Mk I helicopter and Is almed at equipping this vahicle with a number of new equipments in the areas of flight control, electronic displays and computer aided navigation. Particular emphasis is placed on the development of night vision systems for use in helicopters and an experimental pilot's TV system is described. This will be used to explore fundamental aspects of imaging systems prior to the use of an LLTV camera for typical night flying tasks.

AN OPTICAL RADAR SYSTEM FOR OBSTACLE AVOID-ANCE AND TERRAIN FOLLOWING

C. M. Kellington In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975 6 p refs (For availability see N76-30052 21-01)
The operational requirements are discussed for obstacle

avoidance and terrain following systems, the nature of obstacles. the tradeoff considerations involved in the selection of a laser for a system and finally a unique state of the art carbon dioxide (CO2 - 10.6 micron) laser radar system presently under development. Atmospheric penetration properties of the 10 micron radiation which permit moderate weather operation are deduced. The main thrust centers around a technical description of the CO2 system which is called the Laser Obstacle/Terrain Avoidance Warning System (LOTAWS). System parameters e.g., 30 KHz pulse rate, 10 watts average power, 1/3 milliradian beamwidth, 300 nanosecond pulse width, 20 deg x 20 deg field of view, etc., and the methods by which they are achieved are discussed. Other system characteristics including the local oscillator, IF bandwidth, AFC loops, scanner and scan patterns, signal processing, and display to the pilot are discussed. Finally, plans for integration of the LOTAWS with other airborne equipment, including forward looking IR sensors and flight tests beginning in 1974 are outlined

N75-30063 Royal Radar Establishment, Malvern (England) Airborne Radar Group.

IN THERMAL IMAGING SENSORS FOR HELICOPTERS

F. A. Holmes. In AGARD. The Guidance and Control of V/STOL Aircraft, and Helicopters at Night and in Poor Visibility. May 1975. 4 p (For availability see N75-30052 21-01).

The general requirements are considered for night vision sensors which can assist the helicopter crew in their flying and tactical tasks during night operations. It is shown that two classes of sensors are needed, one for the pilot to fly the helicopter and the other for surveillance and target acquisition. The performance parameters required for each class of sensor are analyzed and some of the constraints and compromises on the sensor design are considered. The parameters thus derived show that a common sensor is not compatible for both the flying and target acquisition functions. Some of the vehicle integration and systems interface aspects are discussed to indicate that the final cost-affective choice is most likely to be determined from the overall system considerations rather than that of the IR sensor. Display requirements for both functions are shown to lead to larger units than are currently considered possible for cockpit installation, and matching of the sensor display and operator performances are likely to be the main problem in future

N75-30084 Army Night Vision Lab., For Beivoir, Va. NIGHT VISION IMAGING SYSTEM DEVELOPMENT FOR LOW LEVEL HELICOPTER PILOTAGE

Flight test data of low level night operations in UH-1 helicopters using electro-optical image forming sensors as a pilot flight aid are presented, along with details of the systems used in the investigations. Significant findings and major problem areas driving future work are given along with some present night vision pilot aids. Finally, long range night vision developments for helicopter pilotage are examined.

LOW LEVEL NIGHT OPERATIONS OF TACTICAL HELICOP-

William J. Kennesily In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975–14 p. refs (For availability see N75-30052-21-01) Initial results are presented of the U.S. Army's Low Level

initial results are presented of the U.S. Army's Low Level Night Operations Program, an on-going research program to define Avionic equipment parameters for low level night and adverse weather conditions. Results of the program include quantitative data on the performance of pilots flying at low level with varying levels of avionic equipment augmentation (e.g. none, Night Vision Goggles, FLIR, LLLTV and Rader); simulation and experimental flight test data on conceptual systems (e.g. symbolically augmented visual imaging systems) as well as experimental measurements of various candidate hardware for obstacle detection. The results are utilized to develop preliminary conceptual avionic systems for low level night operations as well as to identify areas in which additional research is required. Future research efforts directed to identified barrier problems are also presented.

TERRAIN AVOIDANCE RADAR USING OFF-BORESIGHT
TECHNIQUES

W. M. Nixon In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975 6 p refs (For availability use N75-30052 21-01)

The two dimensional techniques (height, range) used in Terrain-Following systems were extended to three-dimensional (height, range, distance off-track) by the use of off-boresight processing. Such techniques enable the high data rate volumetric cover required in Terrain-Avoidance (TA) systems to be achieved. Various methods of off-boresight processing are mentioned and the amplitude/phase conversion method used in an experimental UK, monopulse radar is described in some detail. Signal validation techniques which reject signals of small amplitude or which appear from outside the calibrated angular range of the system are described and a possible method of presenting the TA information to a pilot is shown. A simple approach was made to the comparison of amplitude monopules and interferometer systems. It is concluded that there is little difference in the sensitivities of the

two systems in general but that operational constraints will govern the choice between them. Author

DISPLAY FOR APPROACH AND HOVER WITH AND WITHOUT GROUND REFERENCE

Theodor A. Dukos In AGARD The Guidance and Control of V/STOL Alteraft and Helicopters at Night and in Poor Visibility May 1975 8 p. refs (For svallability see N75-30052 21-01) (Contracts DAAB07-72-C-0181, DAAB07-74-C-0051)

The various elements of flight variable information available from an image display are discussed from the point of view of image enhancement by means of superimposed symbology. The significance of a heading reference for accurate positioning is emphasized. Two particular symbology formats are described. For approach and hover unaided by ground based instrumentation, the position information obtainable from an image display is improved by superposition of an electronically stabilized 'terrain marker'. If a radisting point source is available on the ground, quantitative error information can be derived from suitable instrumentation, and the deviation from a nominal point can be displayed superimposed on the image. Additional flight variable information (horizon, sirspeed, climb rate, etc.) is also incorporated.

THE FLIGHT DEVELOPMENT OF ELECTRONIC DISPLAYS
FOR V/STOL APPROACH GUIDANCE

J. N. Bairett and R. G. White In AGARD. The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975–16 p. refs (For availability see N75-30052 21-01).

Two series of flight trials are described which were simed at the development of electronic displays for the approach guidance of V/STOL sircreft in visual and IFR conditions. The first series of trials was flown in the Canadair CL84 and was aimed at extending the approach capability of current operational V/STOL aircreft. The second, flown in the Shorts SC1, investigated the terminal guidance of inter-city VTOL transport aircreft. Performances achieved in the two trials are discussed, and display and flight control system changes are recommended. Author

FLIGHT SYMBOLOGY AUGMENTATION OF SENSOR DISPLAYS

William B, DeBellis and Clarence A, Fry In AGARD. The Guldance and Control of V/STOL Aircraft and Helicopters at Night and In Poor Visibility May 1975. 8 p. refs (For availability see N75-30052.21-0.11).

A study is described in which scales were designed to provide altitude, airspeed, and heading information, and were combined into six candidate flight display formats. Both moving and fixed scales are considered. A repeated measure factorial experiment was designed to use response time and control error as dependent

variables, and display format and scale indication as independent variables. Twelve Army aviators flew each format under static base simulation condition by providing a cyclic control stick response to various scale value changes. It was hypothesized that display formats with markedly differing scale types would strongly affect the pilot's response times and errors, but multivariate and univariate analysis of variances did not verify this hypothesis. There were pronounced differences, but only between individual scale indications. Significant differences in pilot performance between display formats at ose from differences in scale factor rather than from the types of scales. Author

NEW RADIO NAVIGATION AIDS BASED ON TAGAN PRINCIPLES

M. Boehm and E. Coors In AGARD. The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1978. 22 p (For availability see N75-30052 21-01)

The German TACAN family concept with MITAC as an advanced micro-TACAN airborns equipment, FOTAC as a station keeping system, ORTAC-M as a new enroute navigation aid, and SETAC as a landing aid, meets tectical requirements for cargo as well as attack helicopters with reasonable cost of procurement and ownership. Small radio aids for special purposes can be derived from this equipment family (for example, short range omnidirectional beacon (SROB)). The TACAN-mini-beacon SROB works with a 15 Hz-modulation-signal only, and gives omnidirectional azimuth and distance information to an aircraft within 30 NM of the station. The antenna system works without movable parts and generates a rotating cardioid-pattern by feeding RF-energy from an electronic goniometer to fixed radiating elements. Precautions were taken to achieve highly precise horizontal patterns independent of the operating frequency, thus keeping the inherent error of the system F less than or equal to 3 dag over the entire TACAN-band. Experiments under field conditions, using a normal TACAN-airborne-equipment, show the desired operational properties of the system.

N75-30073 Office National d'Études et de Recherches Aerospatiales, Paris (France). A QUIDANCE SYSTEM FOR FIXED OR ROTARY WING AIRCRAFT IN APPROACH AND LANDING ZONES

Jean Besson In AGARD The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility May 1975 8 p refs in FRENCH; ENGLISH summary (For availability ass, N75-30052 21-01)

The proposed system for guiding fixed or rotary wing aircraft in approach and lending zones makes use of the time-frequency principle. It ensures all weather guidance over a few kilometers or, in a more sophisticated form, the ground control of aircraft in approach. It is based on the measurements of the distance separating the moving vehicle from a number of ground stations. Its main advantages are: the use of independent measurements, time multiplexing avoiding frequency cluttering, and the possibility of entering into a multifunction integrated system. Author

THE NUCLEAR LANDING AID FOR HELICOPTERS DURING THE FINAL APPROACH PHASE

Karl H. Busch In AGARD The Guidence and Control of V/STOL. Alteraft and Helicopters at Night and in Poor Visibility May 1975—13 p (For availability see N75-30052 21-01)

A method and procedure are described for landing a helicopter in poor visibility on a beam generated by two gamma-ray sources. The one source gives the pilot the distance on the flightpath to go and to land safely in front of the source, the other gives pitch—and—bank-commands—indicated with a cross-pointer-instrument. The aim was to get a light weight, unsophisticated device with simple ground equipment for which batteries and power generators can be omitted. The prototype-equipment on board the helicopter consists of three gamma-ray detectors and one electronic box to drive the instruments, while the ground equipment consists of one shielding case with both the sources and collimators inside. The center line of the beams can be adjusted to different pitch angles by jurning the case around the horizontal axis.

DEVELOPMENTAL MICRON LABORATORY TEST RE-SULTS

Robert R, Warzynski and George C, Radio In AGARD. The Guidence and Control of V/STOL Aircraft and Helicopters at Night and in Poor Visibility. May 1975. 3 p. (For svailability see N75-30052 21-01)

A moderately accurate, low dost of ownership inertial navigator system, called micro-navigator (MICRON) was developed which will satisfy a wide range of applications including V/STOL sircraft and helicopters. The gyroscope for MICRON is an electrostatic gyro (ESG) operated in a strapdown mechanization. The gyrosperformance in a developmental MICRON system, designated the N57A-1, was verified. The N57A-1 was subjected to heading sensitivity, repeatability, sonraby, shock, vibration, angular rates, dold soak, and mobile tests; over 70 navigation runs were conducted. The N57A-1 demonstrated performance better than the goals of 1 nm/hr and 5 ft/sec for all tests. Author

N78-30077 Boeing Vertol Co., Philadelphia, Pa. HEAVY-LIFT HELICOPTER FLIGHT CONTROL SYSTEM DESIGN

E. D. Diamond and J. M. Davis. In AGARD. The Guidance and Control of V/STOL Aircraft and Halicopters at Night and in Poor Visibility. May 1975. 10 p. (For availability see N75-30052 21-01).

The Army heavy-lift helicopter (HLH) is designed to operate under instrument flying conditions. Dynamic performance, reliability, and survivability considerations, led to selection of a fly-by-wire flight control system with no mechanical backup. Present helicopter handling qualities are generally not acceptable to fly with heavy external loads (up to 35 tons in the HLH case) into unprepared areas under instrument conditions. This mission required development of new helicopter handling qualities including automatic precision hover hold, linear velocity control responses, load stabilization, and automatic approach to hover Efficient hover and low-speed operations necessitated incorporation of a rear-facing station for a load controlling prewmen, who has separate aircraft controls optimized for the precise maneuvaring and trim-hold functions required for cargo transfer Development of the HLH primary and automatic flight control systems is discussed. Pertinent flight simulation and hardware ground- and flight-test results are reported

N75-30078 Royal Aircraft Establishment, Farnborough (England)
HELICOPTER AUTOMATIC FLIGHT CONTROL SYSTEMS
FOR FOOR VISIBILITY OPERATIONS

P. Robinson, J. L. Hollington (Smiths Industries Ltd.), and J Meadows (Smiths Industries Ltd.) In AGARD. The Guidence and Control of V/STOL Aircraft and Hollcopters at Night and in Poor Visibility May 1975—13 p. rofs (For availability see N75-30052 21-01)

Operations are described which halicopters may be required to carry out at night and in poor visibility. Because of the very high pilot work load likely to arise in these situations, it is shown that the helicopter should be equipped with an autostabilization system having a defect-survival capability. One system which meets this requirement was developed for installation and rails in a Ses King helicopter. This system is triplex, with digital computation and has the development potential to include autopilot facilities, sophisticated control techniques, and extended system radundancy. The redundancy philosophy together with salient design and engineering details of the system are described.

N75-30079 Sperry Rend Corp., Phoenix, Ariz AN AUTOMATIC FLIGHT CONTROL SYSTEM FOR A HELICOPTER NIGHT LANDING SYSTEM

R. J. Miller and E. R. Tribken In AGARD. The Guidance and Control of V/STOL Aircraft and Helicopters at Night and in Poor Vialbility May 1975. 9 p. refs (For availability see N75-30052. 21-01)

An automatic flight control system (AFCS) is described which provides the vehicle with handling qualities sufficient for the pilot to perform IFR approach and landings manually, using cockpit displays. It provides absolute maximum operational simplicity so as not to contribute to cockpit workload already increased by the requirement to operate display controls. The AFCS provides stability and command augmentation in pitch, roll and yaw, and the pilot relief functions of pitch, roll, heading hold, and both barometric and radar altitude hold. To provide the improved handling qualities required for the night landing problem, feedback gains and shaping were chosen to attenuate basic aircraft response, and to provide model following of the closed-loop system. The rationale behind the specific aircraft response provided by the system for this mission, the establishment of the operational characteristics and procedures, and the implementation of the system are described in detail. Helicopters at Night and in Poor Visibility May 1975 8 p (For

availability see N75-30052 21-011

The role of fixed and rotary wing VTOL in military missions was expanded with the advent of the light airborne multipurpose system and the sea control ship concepts. A project is described to coordinate the various technologies which impact on the capability of the pilot, the alreraft system and the landing environment, with a goal of an approach, hover, and landing under instrument meteorological conditions. A number of display and automatic control system development programs which will be of significance in the VTOL hover and landing are discussed. Hovering vehicle versatile automatic control is a research and development automatic flight control system which was utilized to develop the requirements for VTOL automatic approach, hover, and landing. The test program to date includes system definition of the vehicle dynamics via a sine wave forcing function method. Curved and straight path approaches were controlled by the airborne digital computer in a simulated microwave landing system environment.

THEORETICAL MODEL FOR VISCOUS INTERACTIONS

Wilbur L. Hankey, Jr. In AGARD Two-Dimensional Shock Wave-Boundary Layer Interactions in High Speed Flow Jun 1975 p 2-13 (For availability see N75-32001 23-01)

Theoretical development employing the boundary layer equations for interacting flows is discussed. Although differences in details exist between the various approaches, a general recipe has evolved for solving this class of flows, and a procedure was developed which nearly guarantees success. The following is a list of the necessary ingredients: (1) boundary layer program; (2) simple inviscid equation; (3) douple the boundary layer with the inviscid flow and solve simultaneously; (4) initiate the program with arbitrary initial conditions and iterate on these until the desired downstream boundary condition is satisfied, and (5) computing the reversed flow region.

N75-32003 Aerospace Research Labs., Wright-Patterson AFB. Ohio.

SPECIAL TOPICS

Wilbur L. Hankey, Jr. In AGARD Two-Dimensional Shock Wave-Boundary Layer interactions in High Speed Flows Jun. 1975 p 13-40 refs (For availability see N75-32001 23-01)

Two integrodifferential equations for the shear stress and heat transfer at the wall are included in place of the set of partial differential equations. The integral form is most useful when employing approximate techniques in that an integration tends to compensate for errors whereas a differentiation magnifies inaccuracies.

Michael S. Holden In AGARD Two-Dimensional Shock Wave-Boundary Layer Interactions in high Speed Flows Jun. 1975 p 44-48 (For availability see N75-32001 23-01)

Most early experimental studies of laminar and turbulent separated regions were conducted in conventional continuous or blowdown tunnels; there is an increasing use of facilities such as shock tunnels, gun tunnels, and Ludwieg tubes to achieve high Reynolds and Mach numbers. These latter facilities are discussed. Heat transfer instrumentation is studied, along with surface and flow field pressure measurements. Total temperature and hot-wire anemometer measurements are considered; finite span effects are also examined.

N75-32005 Calapan Corp., Buffalo, N.Y. SHOCK WAVE-LAMINAR BOUNDARY LAYER INTERAC-TIONS

Michael S Holden In AGARD Two-Dimensional Shook Wave-Boundary Layer interactions in High Speed Flows Jun. 1975 p 48-58 (For availability see N75-32001 23-01)

Qualitative features, strong interaction regime, leading edge bluntness, and surface curvature effects of shock wave-laminar boundary layer interactions were studied. Solutions in the week regime interaction regime, strong interaction regime, and normal pressure gradient were compared to experimental measurements of the integral forms of the boundary layer equations. J.A.M.

THE EFFECTS OF SUFFETING AND OTHER TRANSONIC PHENOMENA ON MANEUVERING COMBAT AIRCRAFT Jul. 1975 278 p. refs

(AGARD-AR-82) Avail: NTIS HC \$9.25

A number of papers were presented dealing with various aspects of buffeting, its causes, and its effects on maneuvering combat aircraft. Some of the aubjusts discussed includes operational problems at transonic speeds, human factors engineering, flow distribution at transonic speeds, dynamic response under buffeting conditions, stability and control, flight tests and wind tunnel techniques, and effects of configuration factors. For individual titles, see N76-14019 through N76-14031.

N76-14018 Royal Aircraft Establishment, Bedford (England).
THE OPERATIONAL PROBLEMS ENCOUNTERED DURING PRECISE MANEUVERING AND TRACKING 608
B. I. L. Hamilton In AGARD The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft Jul. 1975 p. 1-8 (For availability see N76-14018 06-01)

A summary of the main events that occur in air combat and affect its maneuvers and handling limitations was provided. The basic phases and conduct of air combat were first reviewed. The following phenomens that may affect precise maneuvering were defined and described buffeting, wing rock, wing drop or roll off, nose slice or yaw off, nose wander or snaking, pitch up, and departure. All these phenomens can occur in transonic flight and some of them may be found at the lower Mach numbers, where air combat is usually conducted after a protracted engagement. Other factors influencing air combat maneuvering are: control forces, harmonization, and pilot induced oscillations, displays, and workload. The use of the following systems in tracking was described: automatic flight controls and stability sugmentation, direct lift control and direct side force control, reaction controls.

N76-14020 Aerospace Medical Research Labs , Wright-Patterson AFB. Ohio.

AIRCREW CAPABILITIES AND LIMITATIONS

R. N. Slarve In AGARD. The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft. Jul. 1975 p. 9-14 (For availability see N78-14018-05-01)

The pilot factors that can influence aircraft tracking precision during maneuvering flight and the effects of sustained and vibratory accelerations on human performance were reviewed. The effects of various values of buffeting accelerations on vision were presented. It was pointed out that the effect of sustained acceleration on tracking is of far more importance than that of vibration in the current operational environment. Degradation effects of the fullowing factors on pilot performance were discussed: noise, temperature, fatigue, psychological motivation, personal equipment, man-machine interface/control dynamics and configuration. It appears that the best vibration alleviation techniques primarily involve adequate pilot restraints and seating design to minimize excessive relative cockpit pilot motion.

FLOW FIELD ASPECT OF TRANSONIC PHENOMENA

B Monnerie in AGARD. The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft. Jul 1975. p. 18-20 (For availability see N76-14018-06-01).

The serodynamics aspects of flow field over a wing in transonic maneuvering flight were reviewed in order to investigate the problem of buffeting. The case of a two-dimensional sirfoli was first presented, followed by a discussion of three-dimensional flows it was shown that most transonic troubles, and particularly

buffeting, are due to the presence of more or less extended regions of separated flow. These are directly or indirectly related to the shock waves which form on the alteraft in the transonic speed regime. Prediction of what will occur in flight must be based on wind tunnel tests in view of the difficulty to theoretically predict flows with separated regions in the general case. Taking into account the continuous increase in flight Reynolds numbers due to increasing aircraft size, there is a need for higher Reynolds numbers wind tunnels.

DYNAMIC RESPONSE OF AIRCRAFT STRUCTURE

In AGARD. The Effects of Buffeting and other Transonic Phenomens on Maneuvering Combat Aircraft Jul 1975 p. 21-44 (For availability see N78 14018 05 01) (Contract NAS2-6475)

The physical and mathematical problems associated with the response of elastic atrustures to random excitations such as occurs during buffeting and other transonic phenomena were discussed. The following subjects were covered. (1) general dynamic system consisting of the aircraft structure, the serodynamis driving forces due to separated flow, and the aerodynamic forces due to aircraft structural motion, (2) structural and aerodynamic quantities of the dynamic system with special emphasis given to the description of the aerodynamic forces, and including a treatment of similarity laws, scaling effects, and wind Yunnel testing, and (3) methods for rists processing of fluctuating pressure recordings and techniques for response analysis for random excitation. A general buffeting flutter model, which takes into account the Interactions between the separated and motion induced flows was presented. Relaxations of this model leading to the forced vibration model were explained

N76-14023 Air Force Flight Dynamics Lab , Wright-Patterson AFB, Ohio.

STABILITY AND CONTROL STATUS FOR CURRENT FIGHTERS

W. G. Williams and J. L. Lockenour In AGARD. The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft. Jul. 1975. p. 45-53 (For availability see N76-14018 05-01)

The current state-of-the-ait of stability and control technology for maneuvering and prejision tracking was discussed, including basic serodynamics and serodynamic stability and control, flight control system concepts, and methods of prediction and analysis it was shown that the maximum useable maneuvering capability of present fighter streath is often limited to 'g' levels below the maximum serodynamic lift expability by stability, control and handling qualities degradations. In addition, handling qualities degradations often prohibit precision tracking although grows maneuvering may still be possible. Automatic flight control systems (stability augmentation and command augmentation) are being employed to correct many of the bare airframe deficiencies and additional capability is being provided by advancements in the fire control systems.

N76-14024 Air Force Flight Dynamics Lab . Wright-Patterson AFB, Ohio.

STABILITY AND CONTROL POTENTIAL FOR FUTURE FIGHTERS

J. L. Lookenour and W. G. Williams. In AGARD. The Effect of Buffeting and other Transome Phenomena on Manauvering Combat Aircraft. 1975. p. 54-62 (For availability see N76-14018. 05-01).

Advanceri stability and control concepts aimed at further improving maneuvering and precision tracking were presented. The proposed new modes of control, methods of generating the required forces and moments necessary to produce the motions, flight control system concepts to implement the maneuvering modes, and the additional impact of pilot factors were discussed. Methods of prediction and analysis were also presented, and recommendations were made regarding the concepts and areas of analysis which are considered to be most important. Author

BUFFET DEFINITION AND CRITERIA

In its The Effects of Buffeting and other Transonic Phenomena on Manauvering Combat Aircraft Jul 1975 p 63-83 (For availability see N76 14018 05-01)

Two areas related to aircraft buffeting were discussed: wing and tail buffet, and bomb bay buffeting in the first area, basic definitions were given, followed by buffeting criteria for lighter and transport aircraft, classification of wing flow and buffeting for various types of wings, buffet onset and the severity of buffeting, and tall buffeting. It was concluded that (1) for bubble flows, the largest excitation is found just upstream of the reattachment point, (2) for slender wings with sharp leading edges the buffeting is light but just measurable, (3) for swept wings buffeting measurements must be made on rigid models Bomb bay buffeting was defined as the specific dynamic behavior of an aircraft when excited by forces of random and harmonic nature due to flow separation in open bays or cavities. A remarkable large change in mean pressures occurs for bays with a length/depth ratio of about six, for which drag reises

N76-14026 Aeronautical Systems Div., Wright-Patterson AFB,

BUFFET ANALYSIS

P. J. Butkewicz. In AGARD. The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft Jul. 1975

p 84-90 (For availability see N76-14018 05-01)
The methods available for transonic buffer analysis were reviewed. The analysis methods were divided into two groups. experimental model testing including associated empirical prediction methods, and semi-empirical or theoretical procedures which require some flow field calculations. Due to the complexity of the transonic flow about wings experiencing unsteady separation, wind tunnel testing is the primary tool for obtaining detailed information about the buffet intensity. A serious problem however exists in applying the results to full scale due to improper boundary layer modelling at the relatively low test Reynolds numbers. A buffet onset prediction method suitable for theoretical analysis was outlined and is primarily applicable to thick, aft loaded sirfolls which display a significant pressure rise from the shock and trailing edge and which therefore have a tendency for rear separation

N76-14027 Aeronautical Systems Div., Wright-Patterson AFB,

BUFFET FLIGHT TEST TECHNIQUES

P. J. Butkewicz. In AGARD. The Effects of Buffeting and other Transonic Phenomena on Manuscring Combat Aircraft 1975 p 91-98 (For availability see N75-14018 05-01)

Buffet instrumentation and flight test techniques were discussed. Details of the instrumentation installed for buffet tests of a F-106A aircraft were given. In general, flight instrumentation for buffet tests should include: static pressure taps, total pressure and boundary layer rakes, accelerometers, strain gauges, aircraft attitude sensors, high speed camera and wing tufts. Particular attention must be paid to the application of wing tufts for flow visualization and for the mounting of the camera. The schedule used in buffet flight testing should incorporate that sequence of aircraft configurations and Mach-altitude conditions which will provide the most rapid collection of data based on (1) the time required to attain the desired aircraft configuration and test condition, and (2) the aircraft modification time required for the subsequent configurations. Author

N76-14028 Royal Aircraft Establishment, Bedford (England) LIMITATIONS IN THE CONRELATION OF FLIGHT/TUNNEL BUFFETING TESTS

D. G. Mabey In AGARD. The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft Jul. 1975

p 99-104 (For availability see N76-14018 05-01)

Some possible sources of discrepancies between flight and wind tunnel buffeting measurements were discussed. The single, most serious causes of discrepancies is probably the failure to represent on the model the development of flow separations on the actual aircraft. The best way to improve future predictions is to test as large a model as possible, including the repesentation of gaps, surface roughness, etc., at as high a Reynolds number as possible, and then to insist on an extensive flight program. Other sources of discrepancies include: flight test measurement errors, visualization of areas of separated flows, influence of tunnel characteristics on model buffeting, measurement of buffeting.

H Max In AGARD The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft Jul 1975 p 104-107 (For availability see N76-14018 05-01)

Data concerning the effects of the geometrical configuration parameters. Revnolds number, external stores and supercritical wing layout of an aircraft on its buffet boundaries and the buffet intensities was presented. The following geometrical parameters were considered wing aspect ratio, taper ratio, aweep angle, relative maximum thickness of the wing root section, and relative maximum camber of the wing section. The effects of these parameters on buffeting were shown graphically. An equation was given from which the light buffet lift coefficient may be estimated for a given wing at specific transonic Mach numbers and Reynolds numbers

N76-14030 Aentalia, Turin (Italy). IMPROVEMENT OF AIRCRAFT BUFFET CHARACTERIS. TICE

G Bucciantini In AGARD The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft Jul. 1975 p. 108-110 (For availability see: N76-14018-05-01)

A series of provisions which can be taken to improve the buffet characteristics of an aircraft wore described. These include maneuver slats and flaps, strakes, aerodynamic flxing (notch, sawtooth, fence, etc.), and vortex generators. The effects of these devices were shown graphically A separate discussion on the possibility of tailplane buffet and suitable remedial actions was

N76-14031 Advisory Group for Aerospace Research and Development, Paris (France).

CONCLUSIONS AND RECOMMENDATIONS

In its The Effects of Buffeting and other Transonic Phenomena on Maneuvering Combat Aircraft Jul 1975 p 111-112 (For availability and N76-14018 05-01)

General conclusions and specific recommendations on aircraft buffeting problems were presented. These include the need for (1) a total system analysis to determine the effects of buffeting during maneuvering flight. (2) improved methods of viscous flow field and separation prediction. (3) comparing results from existing buffet onset prediction with wind tunnel and flight test data to determine their range of applicability. (4) better understanding of wind tunnel perturbation effects, (5) understanding of high speed stall progression, (6) identification of the interaction between the random aerodynamic driving forces and the structural response forces. (7) understanding the basic and interacting phenomena on existing and emerging fighters, and (8) isolating the effects of the various parameters more clearly, broadening the spectrum of the various parameters, and giving a better understanding of the physical process of buffeting

Measuring units for wind tunnels of the Modane-Avrieux Centre were gradually equipped with minicomputers for insuring the following functions measurement acquisition management, test control and monitoring, and automatic operations. Multitask type software offers a great flexibility for dialogue with the experimenter and allows an exchange of informations with the outside, at a rate close to that of a stand alone computer. The

whole system is operational since April 1975. Three applications are described two dimensional profile tests, convertible rotor tests with real time simulation of rotor tilting, and device for weighing missiles close to the aircraft with a view to calculate step by step the imissile relative trajectory (captive trajectory method). These examples outline the functions entrusted to the computers associated to measuring units, the loads they can withstand, and the limits of their possibilities.

SOME EXPERIENCES WITH THE EXPLOITATION OF MEASUREMENTS OF THE PERTURBATION FIELD IN A WIND TUNNEL TO IMPROVE SIMULATION

W. R. Sears In AGARD Numerical Methods and Windtunnel Testing Oct. 1976 4 p Prepared in cooperation with Calapan Corp. (For primary document see N77-11989 03-01) Avail: NTIS HC A10/MF A01

The essential feature is that both the flow within the tunnel and the computed exterior field are iteratively adjusted to achieve the matching. The tunnel flow is adjusted by mechanical changes of tunnel wall geometry, for example, by varying the pressures in subdivided plenum chambers surrounding the working section and communicating with the tunnel through porous wells or slots. The exterior flow field is adjusted by altering the boundary values prescribed at S, on the basis of measurements of flow perturbation distributions at or necr S.

AUTOMATIC CONTROL OF A TRANSONIC WIND YUNNEL
WITH A REAL-TIME COMPUTER SYSTEM

J. A. Gunn and J. P. Christopher, Jr. In AGARD Numerical Methods and Windturinel Tosting. Oct. 1976. 6 p. ref. (For primary document see N77-11969 03-01). Avail: NTIS HC A10/MF A01

The aerodynamic wind tunnel (4T) real time control and display system is a computerized system which has increased the productivity of the tunnel 4T tests by providing real time displays of test conditions, test condition monitoring, and automatic control. The system is built around a PDP 8/E minicomputer which has a 16K word memory and a hardware floating point processor. The system uses standard tunnel measurements to calculate stream and plant parameters. The program, which is written in the FORTRAN 4 language, is executed three times per second. Computer-driven video displays provide tunnel operators and other control room personnel with test conditions such as Mach number, Reynolds number, and dynamic pressure. The real time system monitors all test parameters, continually checks to determine if test conditions are as requested, and informs the operators of the current plant and test conditions status via the status panel. The real time system automatically controls the test section well porosity, ejector flaps, wall angle, the tunnel stagnation pressure for most conditions, and the Mach number in the range from 0.2 to 0.9.

Numerical methods and experimental techniques for the simulation of separation trajectories of external powered and unpowered stores at low and high speed are reviewed. For the theoretical simulation, potential flow methods are used to calculate the quasi-steady loadings on the store while the trajectory itself is determined by solving the equations of the 6-degree-of-freedom. motion. Sessed on the experience of numerous systematic experimental studies gained with the rigid loads and the freedrop technique for unpowered stores, the advantages and limitations of different wind tunnel techniques are demonstrated including a critical discussion of scaling effects.

THE IMPORTANCE OF EXPERIMENTALLY-DETERMINED CLOSURE CONDITIONS IN TRANSONIC BLADE-TO-BLADE PLOWS CALCULATED BY A TIME-DEPENDENT TECH-NIQUE

M. Couston In AGARD Numerical Methods and Windtunnel Teeting Oct. 1976 23 p refs (For primary document see N77-11969 03-01)

Avail: NTIS HC A10/MF A01

The use of a time dependent technique to determine inviscid blade-to-blade flow in the transonic regime for exial turbomachines is faced with the problem of closure conditions. The importance of a Kutta condition in subsonic flow calculations is well known but for transonic blades the problem is still more complex. The quasi-discontinuous character of the flow through shock waves and Prandti-Meyer expansions is then superimposed on the viscous effects which dominate near the trailing edge. In order to get more information about the importance of this problem, a

comparison between detailed measurements and calculations is presented. The calculations were performed for several trailing edge flow approximations including experimentally determined

NUMERICAL SIMULATION OF THREE DIMENSIONAL TRANSONIC FLOW INCLUDING WIND TUNNEL WALL **EFFECTS**

W Schmidt, H.-W Stock, and W Fritz In AGARD Numerical Methods and Windtunnel Testing Oct 1976 8 p. refs (For primary document see N77-11969 03-01) Avail NTIS HC A10/MF A01

Numerical methods and their practical implementation are presented to compute steady transonic flow fields about wings and wing-body combinations in transpose flow including viscous effects as well as wind tunnel wall effects. The transonic small disturbance potential equation is solved by a mixed finite difference scheme. Wind tunnel wall boundary conditions are incorporated in the relexation procedure by use of the classical wall condition equations. The three dimensional boundary layer equation is solved by an integral prediction method. Solving potential equation and boundary layer equation Iteratively, viscous effects are accounted for by means of the displacement thickness concept. Results showing the influence of Reynolds number and Mach number on pressure distribution and shock position are shown.

FOURIER ANALYSIS AND THE CORRELATION OF SPEED WITH NONSTATIONARY AERODYNAMICS (ANALYSE DE FOURIER ET CORRELATION DE VITESSE EN AERODYNAM-IQUE INSTATIONNAIRE]

Plerre Gougat and Francoise Martin In AGARD Numerical Methods and Windtunnel Testing Oct. 1976 7 p refs in FRENCH (For primary document see N77-11969 03-01)

Avail: NTIS HC A10/MF A01

Transition from a laminar to a turbulent state begins with the appearance of natural instabilities made up of sine waves of uncertain intermittance in the midst of the boundary layer. The response of the boundary layer to a local vibration in the wall is studied in order to suppress the uncertain character of the Intermittance. The sine wave of deformation of the wall is obtained with the aid of a lock-on displacement loop. The signal of speed fluctuations in the boundary layer is obtained with a hot wire anemometer. These two data are treated separately by real time analysis which permits measuring the harmonic rate of the signal of deformation to determine the spectral density of the power of the fluctuations of speed. The simultaneous treatment of two signals is used for real time correlation. To this correlation is associated a Fourier transformation which provides the mutual spectrum of the two signals. A magnetic recording stores the signals and reads them again at a speed which facilitates the observations and study of the in-Transi. by A.H. stantaneous phenomena.

An investigation of aerospace research and development emphasizing the area of short takeoff (STOL) aircraft in Canada was presented. Research into the military sir material requirements and the governmental support given was discussed. The government policies concerning research into STOL aircraft and

its military as well as commercial possibilities were studied. Military application of the TEA-CO2 laser was considered, including radar type applications and use of the laser as a weapon. For individual titles, see N77-14983 through N77-14988.

N77-14983# Department of National Defence, Ottawa (Ontario) CANADIAN MILITARY AIR MATERIEL REQUIREMENTS D W Gors In AGARD 11th AGARD Ann Meeting Feb 1976 p 11-14 (For primary document see N77 14982 06-01) Avail NTIS HC A04/MF A01

Cold and snow are but two characteristics of Canada which must be accounted for in stating military requirements. The northern magnetic pole is in Canada, and aurora borealis displays are frequent, affecting communications and navigation. When winter's grip relaxes, the insect population emerges making life barely livable without some form of protection. Most of these characteristics must be catered to in stating requirements for material, as they affect all facets of equipment performance. from aircraft range through special navigation requirements through special environmental protection requirements. In addition to purely Canadian conditions, the conditions related to operations in Europe and the material requirements are superimposed. Among these are the extremely corrosive atmosphere which proved particularly troublesome, and less tangible but equally serious differences in the stresses due to a difference in the turbulence regime, differences in bird hazards and so on. As some of the forces are also assigned to the United Nations in the Middle East, conditions of heat, sand and corrosive atmosphere must also be considered in this application of our equipment in this environment Author

HINGELESS ROTORCRAFT FLIGHT DYNAMICS

Kurt H. Hohenemser (Washington Univ. St. Louis) and Robert A. Ormiston, ed. (Army Air Mobility R and D Lab. Moffett Field, Calif.). Sep. 1974. 50 p. refs.

(AGARD-AG-197, AGARDograph-197) Avail NTIS HC \$3.75 The state of hingeless rotorcraft research and development in the NATO countries as of 1973 is described. The scope of this report is limited to flight dynamics since most of the hingeless rotorgraft problems have occurred in this area. The special place of the hingeless rotorcraft within the family of rotorcraft is considered. The chapter on the history of hingeless rotorcraft. describes the hingeless rotor research and development of the various rotorcraft manufacturers and the hingeless rotor research at government laboratorios and universities. A hierarchy of dynamic concepts from isolated blade dynamics to complete rotor/body dynamics is introduced. The effects of the basic rotor design parameters on flight dynamics are traced and certain hingeless rotorgraft problems are treated in some detail. A special chapter is devoted to the alleviation of hingeless rotor flight-dynamics problems by feedback control systems. Analytical modeling techniques, mathematical analysis techniques, and model and flight testing techniques for hingeless rotorcraft are discussed

PREDICTING THE MAXIMUM LIFT OF JET-FLAPPED WINGS

David J. Moorhouse In AGARD V/STOL Aerodyn. Oct 1974 9 p. refs (For availability see N75-13795 05-02)

A method for predicting the maximum lift of jet flap configurations is presented. The three parts of the process are described. A theoretical expression for the increment in maximum lift due to blowing on jet-flapped airfolls was obtained that was based on the assumption of a leading-edge stall. For practical application a three-dimensional theory is required, with suitable corrections for finite aspect ratio and part span flaps. The expression shows agreement with measured results for pure jet flaps, internally blown flaps, and upper surface blown flaps. It was determined that the results are independent of the actual presence of a leading edge stall, independent of the sweep angle, and applicable to aspect ratios greater than approximately three.

WIND TUNNEL INVESTIGATION OF THREE POWERED LIFT STOL CONCEPTS

R. F. Osborn and G. S. Ostes In AGARD V/STOL Aerodyn. Nov 1974 12 p. refs (For svallability see N75-13795 05-02)

A comprehensive, parametric wind tunnel investigation of three short takeoff and lending aircraft concepts was conducted. The three STOL configurations were: (1) the externally blown flap (EBF), (2) internally blown flaps (IBF), and (3) the mechanical flap/vectored thrust (MF/VT). Wind tunnel model characteristics are shown as well as the details of the high lift devices tested. The effect of engine location is discussed and is shown to be the dominant factor in EBF and MF/VT powered lift performance. Wing sweep and aspect ratio effects on lifting performance are analyzed. Performance in ground effect is covered using the test data collected. Incremental changes in the lift, drag, and pitching moment characteristics resulting from in-ground effect operation are explained. A comperison of the aerodynamic performance of the three powered lift systems is included.

JET FLAP
R H. Wickens /n AGARD V/STOL Aerodyn. Oct. 1974 23 p

refs (For availability see N75-13795 05-02)

The aerodynamic characteristics of externally blown flaps (EBF) are presented for configurations of the quasi-two dimensional and reflection-plane type. Force and surface pressure measurements have shown that significant lift increments can be realized by external blowing, and that the spanwise effect of this increase extends outward from the hacelle location. The effective stream tube dimension of the additional lift can be a significant fraction of the wing span. Downstream flow surveys have shown that the presence of mixed regions of propulsive and vortex flows is typical of the EBF, particularly for multi-engined finite wing configurations. The characteristics of wake measurements downwind of a half-model of a multi-engine aircraft of the EBF type are described.

THE FLOW AROUND A WING WITH AN EXTERNAL FLOW
JET FLAP

P. R. Ashill and D. N. Foster In AGARD V/STOL Aerodyn Oct. 1974 13 p. rofs (For availability see N75-13795 05-02)

The main features of the flow around a wing with an externally blown jet flap are discussed. Measurements were made, under wind-on and wind-off conditions, on a half model of a wing-fuselage with an injector powered nacelle mounted under the wing. Analysis of the velocity distributions measured in the jet at the trailing edge of the flap suggests that the turning and spreading process is sensibly independent of forward speed. The sweepback offect on the spanwise distribution of momentum towards the wing tip is investigated. It was determined that the

spanwise distributions of lift and pressure drag, derived from static pressure measurements made under wind un conditions. exhibit a pronounced nonuniformity in the vicinity of the nacelle. It is stated that the jet flap effect on the total lift is small.

N75-13802 Canadair, Ltd., Montreal (Quebec). INVESTIGATION OF EXTERNALLY BLOWN FLAP AIRFOILS WITH LEADING EDGE DEVICES AND SLOTTED FLAPS
Fotia Mavriplis and David Gilmore In AGARD V/STOL Aerodyn.
Oct 1974 12 p refs (For availability see N75-13795 05-02)

An investigation was conducted to provide information on the aerodynamics of externally blown flap systems and to establish the correspondence of such systems, in which the flap is blown by a jet of circular cross section, with two dimensional jet flaps. Wind tunnel tests were conducted with a two dimensional high lift wing model and a tip turbine fan having a diameter-to-wing chord ratio of 0.365. A semi-empirical two dimensional method is also presented which is an extension of the theory for thin multi-element airfolls and a nonlinear jet geometry. The measured data provided useful empirical relationships for estimating the two dimensional C sub L max and C sub D.

EXPERIMENTAL HIGH LIFT OPTIMIZATION OF MULTIPLE ELEMENT AIRFOILS

Bjoern L. G. Ljungstroem In AGARD V/STOL Aerodyn. Oct. 1974 16 p refs (For availability see N75-13795 05-02)

The application of two dimensional testing and two dimensional wind tunnel techniques for experimental high lift investigations is discussed. The tests conducted on geometrical variations of double and triple slotted mechanical flaps are described. It is shown that an optimum slat position corresponds to a flow with relatively little interaction between the slat wake and the main wing and flap boundary layers. Similar results were also obtained for the trailing edge, where it is found that the different viscous layers should be kept essentially separated from each other. The interrelationship between the flow over the leading-edge slats and that over the trailing-edge flaps is analyzed. The calculation methods consist of a potential flow method and a method in which the boundary laver effects are considered

N75-13809 British Columbia Univ. Vancouver THE AERODYNAMICS OF TWO-DIMENSIONAL AIRFOILS WITH SPOILERS

G. V. Parkinson, G. P. Brown, and T. Jandali. In AGARD. V/STOL Aerodyn. Oct. 1974 10 p. refs. Sponsored by Defende Res. Board of Canada (For evallability see N75-13795 08-02)

The development of three incompressible potential flow methods for two dimensional strfolls with upper surface spoilers is discussed. A linearized free stream theory is used to predict the steady and transient lift on thin, single-element airfolls of arbitrary incidence, camber, and thickness, with spoilers of arbitrary position, height, and inclination. Theories for determining the pressure distribution on thick airfolls are reported. Wind tunnel measurements of steady and transient lift and pressure distribution have been made using two different airfoil profiles with several different spoiler sizes, positions, and inclinations.

JET LIFT PROBLEMS OF V/STOL AIRCRAFT

J. Baiche In AGARD V/STOL Aerodyn refs (For availability see N76-13795-05-02) Oct 1974 18 p

The effect of jet lift interference on the design of jet-supported V/STOL aircraft is discussed. The basic flow problems which are assumed to be valid for all types of V/STOL aircraft are analyzed. The operational aspects of military V/STOL aircraft are examined. The specific problems of V/STOL operation involving transition flight, pitch control and stability, lateral /direction, control and stability, hovering flight, and recirculation of the jet exhaust are presented

SIDESLIP IN VIOL-TRANSITION FLIGHT: A CRITICAL FLIGHT CONDITION AND ITS PREDICTION IN SIMPLE WIND TUNNEL TESTS

B. Eweld In AGARD V/STOL Aerodyn.

refs (For evaluability see N75-13795 05-02)

Wind tunnel tests were conducted to analyze the performance of the VAK 191 B VTOL aircraft during transition flight. Tie procedures for conducting the wind tunnel tests are explained It was determined that the ratio of jet momentum and free stream momentum is the most important scaling parameter for the influence of the jet on the external flow field. The results of the wind tunnel tests are compared with flight test results to determine the extent of agreement. Based on the wind tunnel tests, development of the aircraft automatic sititude control system and a system for pilot training in the flight simulator was

N75-13813 National Aerospace Lab., Amsterdam (Netherlands). A METHOD FOR THE CALCULATION OF THE FLOW FIELD INDUCED BY A JET EXHAUSTING PERPENDICULARLY INTO A CROSS FLOW H. Snel In AGARD VISTUL Aerodyn. Oct. 1974 16 p refs

(For availability see N78-13795 05-02)

A description is given of a method for the calculation of the potential flow field arising from the interaction of a turbulent let with a uniform free stream. The method is applied to the case of a jet moving perpendicularly into a cross flow. The model assumes the jet to entrain free stream mass together with its free stream momentum. The decay of axial velocity in the jet is used as empirical input. The geometry of the jet surface and jet entrainment follow from the model. A set of quadratic equations, describing mass and momentum transfer from the exterior flow to the jet, consistent with equations used for the jet model, yields the normal velocity distributions and the source strengths of the surface panels

MEASUREMENT OF TILT ROTOR VTOL ROTOR WAKEAIRFRAME GROUND AERODYNAMIC INTERFERENCE FOR

APPLICATION TO REAL TIME FLIGHT SIMULATION

Troy M Gaffey (Bell Helicopter Co., Ft. Worth, Tex.) and Martin D. Meisel. In AGARD. V/STOL Agrodyn. Oct. 1974. 12 p. refs (For availability see N75-13795 05-02) CSCL O1C

The hover and low speed rotor wake-airframe-ground aerodynamic characteristics of the XV-15 tilt rotor research aircraft were determined in wind tunnel tasts of a scale model. Results of the wind tunnel tests were applied to real flight time simulation. The principal findings of the wind tunnel tests are summarized The effect of aerodynamic interference on the handling qualities of the strotaft is analyzed it was determined that serodynamic interference effects are significant in hover and at low speeds, with the influence being more pronounced in ground effect than out of it. At airspeeds above 60 knots, aerodynamic interference does not have a significant affect on handling characteristics.

US AIR FONCE VISTOL AIRCRAFT AERODYNAMIC PREDICTION METHODS

Henry W. Woolard In AGARD V/STOL Aerodyn. Oct. 1974 14 p. refs (For evallability see N75-13795 05-02)

Ansiytical methods for the prediction of the serodynamic characteristics of V/STOL aircraft are reviewed. The serodynamic characteristics of short takeoff aircraft are discussed with emphasis on high lift systems using internally-blown flaps, under the wing externally-blown flaps, and machanical flaps combined with thrust vectoring. The power-induced serodynamics of lift-jot, lift-fan, and vectored thrust V/5TOL sircraft operating in hover and transition flight regimes are examined. Emphasis is placed on describing selected methods that employ rational analytical modeling of the real serodynamics in conjunction with empirical modifications as required.

AIRCRAFT STALLING AND BUFFETING

Feb 1975 189 p. refs. In ENGLISH, partly in FRENCH (AGARD-LS-74). Avail. NYIS. HC \$6.26

Lectures on the subject of aircraft stalling and buffeting are presented. The scope of the presentations involves recent developments in the understanding of the fluid dynamics of aerodynamic stalling and buffeting, the dynamic response of the alloraft, and techniques for buffet prediction, with consideration of the implications for aircraft design for individual titles, see N75-22281 through N75-22287

N75-22281 Royal Aggraft Establishment, Bedford (England) AIRCRAFT STALLING AND BUFFETING: INTRODUCTION AND OVERVIEW

G R Taylor In AGARD Aircraft Stalling and Buffeting Feb 1975 18 p refs (For availability see N75-22280 14-02)

The phenomena of aircraft stalking and buffeting are and lyzed with respect to the influence exerted by various aerodynamic configurations. Variations of the lift coefficient of a wing with changes in angle of incidence and Mach number are examined to show the effect on the stalling characteristics. Aerodynamic designs which provide a uniform pressure distribution as a method

for delaying the onset of serodynamic stall are described. Block diagrams are developed to show the relationships of serodynamic forces and serodynamic effects for structural buffeting and rigid-body dynamics. The limitations imposed on aircraft maneuverability by the onset of aerodynamic stall are explained. Author

REMARKS ON FLUID DYNAMICS OF THE STALL
A. M. O. Smith In AGARD Aircraft Stelling and Buffeling Feb. 1975 33 p refs (For availability see N75-22280 14-02)

An analysis of serodynamic stalling based on fluid mechanics phenomena is presented. Emphasis is placed on the flow separation which occurs during a stall and flow photographs of such events are provided. Limits to pressure rise for both laminar and turbulent flows are given, as well as their general theory.

The effects of Reynolds number, Mach number, and sirfoll shape on flow separation are examined. Diagrams of the conditions existing in full aircraft stall and buffeting process are developed. The problem of calculating flows with separation is discussed.

N75-22283 Booing Co., Seattle, Wesh PREDICTION AND ANALYSIS OF THE LOW SPEED STALL CHARACTERISTICS OF THE BORING 747

William McIntosh and John K. Wimpress In AGARO Aircraft Stalling and Buffeting Feb. 1975 21 p (For availability see N75-22280 14-02)

Wind tunnel tests for estimating the stall speed of the Boeing 747 aircraft were conducted. The test results were adjusted to full scale flight values using correlation factors developed from other transport aircraft designs. Flight results showed a reasonable degree of success in predicting stall speeds. A further analysis was made to show the effects of percelastic and airplane dynamics in accurately predicting aerodynamic

Jacky Leynaert In AGARD Airframe/Propulsion Interference Mar 1975 11 p refs in FRENCH (For availability see N75-23485

The definition of the interaction terms between the air intake and the airframe, and the theoretical and experimental tools used to study the problem for subsonic or supersonic aircraft are presented. Some examples of the influence of a nonuniform upstream flow on the internal flow characteristics of supersonic intakes are given, and some means of adjusting the inlet to a nonuniform flow, mainly for flight with incidence or yaw, are Author

N75-23487 Northrop Corp., Hawthorns, Calif. A CRITERION FOR PREDICTION OF AIRFRAME INTEGRA-TION EFFECTS ON INLET STABILITY WITH APPLICATION TO ADVANCED FIGHTER AIRCRAFT

Gordon R. Hall In AGARD Airframe/Propulsion Interference Mar 1975 15 p refs (For availability see N75-23485 15-02)

A simple criterion for the prediction of the effects of aircraft external flow field on installed inlet stability is presented. Wind tunnel data obtained from model tests of an advanced fighter stroisit are used to provide a base for discussion of installed inlet instability and to demonstrate the instability criterion. Specifically, two sources of supersonic inlet instability are identified, the instability mechanism is discussed and an instability criterion is defined, and application of the criterion is demonstrated. The sources of instability include ingestion of separated fuselage houndary layer at high aircraft attitude and ingestion of a vortex generated by a wing leading edge extension at negative attitude. A common stability criterion accounting for the affect of freestream Mach number, aircraft attitude, and inlet mass flow ratio is postulated and confirmed by available data. This same criterion is discussed in relation to observed cases of subsonio inlet instability and inlet instability resulting from slipstream ingestion. Application of the criterion to evaluate the effects of configuration changes on inlet stability boundaries is demon-

THE MEASUREMENT OF THE TRANSONIC SPILLAGE DRAG OF A SUPERSONIC INTAKE

S.A.M. Thornley and E.C. Carter. In AGARD. Airframe/Propulsion. Interference Mar 1975 13 p refs (For availability see N75-23485

The technique is described in current use at the Aircraft Research Association for the measurement of the transonic spillage drag of a two dimensional, ramp intake. The method requires the calibration of the intake duct system for both mass flow and exit momentum. The technique is equally applicable to supersonic testing. The achieved repeatability of the measurements allows intake configuration differentiation to + or + 1% in aircraft drag for a typical supersonic fighter aircraft at high subsonic speed. Theoretically based culculations show satisfactory agreement with the measurements both for a range of intake mass flow and for intake ramp angle changes. The technique is economical and suitable for routine testing. General comments on the merits of methods available for the measurement of spillage drag using the balance mounted and whole model technique are presented together with recommendations for further technique development Author

N76-23499 Grumman Asionpace Corp., Bethpage, N.Y. AN EXPERIMENTAL INVESTIGATION OF THE COMPONENT DRAG COMPOSITION OF A TWO-DIMENSIONAL INLET AT TRANSONIC AND SUPERSONIC SPEEDS Clifton J Callahan In AGARD Airframs/Propulsion Interference

Mar 1975 16 p refs (For availability see N75-23485 15-02)

An experimental study was performed to establish the separate drag force contributions of the principal components of a rectangular, two-dimensional, external compression type. supersonic air induction inlet system. Concurrently, inlet system performance was measured in terms of engine face total pressure recovery and spacial flow distortion, and the possibility for tradeoff between inlet system drag and performance was explored. A scale model of the forebody, including air inlet and duct systems. of an advanced, twin engine, strike aircraft was employed for the study. The wind tunnel model arrangement utilized a dual-balance technique to measure forebody and the infet forces separately. The effects on the air induction system and vehicle forebody due to inlet component changes and varying propulsion air flow requirement were identified. The major intet variables in the investigation included cowling lip and sidewall geometries. boundary layer bleed and air bypass exhaust configuration, and compression surface deflection schedule. The wind tunnel testing was conducted in closed circuit, continuous flow test facilities over a full range of supersonic and transonic speeds and representative ranges of vehicle angles of strack and sideslip Three significant aspects of the program are addressed injet and vehicle configuration integration, wind tunnel model arrange ment for force data measurement, and measured drag and performance results. These data can be broadly divided according to cowling, side wall, and bleed/bypass effects in order to display major trends in drag and performance for the investigated transonic and supersonic speed regimes

N75-23490 National Agrospace Lab , Amsterdam (Netherlands). JET INTERFERENCE OF A PODDED ENGINE INSTALLA-TION AT CRUISE CONDITIONS

B Munniksma and F Jaarsma In AGARD Airframe/Propulsion Interference Mar 1975 16 p refs (For availability see N75-23485

The results of an experimental wind tunnel test program on the wing-pylon-bypass engine combination of the Airbus A 300 B similars are presented. Only serodynamic interference due to the engine jet was considered For determining the interference drag due to the engine jet as well as to have the possibility to extrapolate the test results from model reference conditions to full scale a test scheme was developed. To prove the validity of the assumptions of this scheme several intermediate steps were made. As the engine jet-sirframe interference is mutual, also effects of the external flow on the internal engine nozzle flow causing engine shifting has to be considered in order to estimate the magnitude of this influence of the external flow field a two-dimensional model of the fan nozzle has been tested using an optical technique From these tests the specific features of the fan nozzle flow field ranging from subgritical via supercritical to choked conditions are described

EFFECT OF EXTERNAL CONDITIONS ON THE FUNCTION. ING OF A DUAL FLOW SUPERSONIC NOZZLE EFFET DES CONDITIONS EXTERIEURES SUR LE FONCTIONNE MENT D'UNE TUYENE SUPERSONIQUE DOUBLE-FLUX Guy DeRichemont and J Delery (Office Natl d'Etudes et de Rech Aerospatiules, Parisl In AGARD Airframe/Propulsion Interference Mar 1975 14 p refs in FRENCH ENGLISH summary (For availability see N76-23485 15-02)

The design of versatile military aircraft implies a very careful study of the propulsion system, taking into account interferences with the external flow A possible solution to this difficult problem of adoptation is that of a dual flow system consisting of two nozzles with variable sections. Flow regimes where the primary jet impiges on the secondary nozzle are considered. The evolution is analyzed of the phenomena when the external pressure and the distance between primary injector exhaust plane and the nozzle exit are varied. This experimental study shows the influence of the external conditions upon the functioning of the nozzle Theoretical methods are given which allow a reasonable prediction of nozzle performance under such conditions

N75-23492 LTV Aerospace Corp. Dallas, Tex. Vought Systems SUSSONIC BABE AND BOATTAIL DRAG, AN ANALYTICAL **APPROACH**

J. K. Quermann. In AGARD. Airlrame/Propulsion Interference Mar 1975 12 p refs (For availability see N75-23485 15-02) Methods of subsonic potential flow were applied to the

calculation of base and boattail drag. For configurations with a base the Korst method was extended to subsonic flow by

incorporating a standard family of free streamline shapes and a semi-empirical scheme for selecting the total pressure on the dividing streamline. The potential flow around the shape defined by the body, free streamline, and jet establishes the base and

boattail pressures. Significent parts of the drag associated with the base actually appear on the boattail. In the absence of a base, the effect of the jet shape is felt by the boattail. With an underexpanded supersonic jet a portion of the thrust which would otherwise be lost in external expansion is recovered on the boattail. The fraction recovered drops rapidly with increasing jet pressure ratio. Results are compared with flight and wind tunnel tests on the Vought A-7 Airplane.

THEORY OF MIXING PLOW OF A PERFECT FLUID AROUND AN AFTERBODY AND A PROPULSIVE JET [COUPLAGE ENTRE L'ECQULEMENT AUTOUR D'UN ARRIERE-CORPS ET LE JET PROPULSIF EN THEORIE DE FLUIDE PAR-EALT]

Roland Maria Sube. Jean-Jacques Chattot, and Georges Gillon In AGARD. Airframe/Propulsion Interference. Mer 1975. 12 p. refs. In FRENCH. ENGLISH summery (For availability see N75-23485 15-02).

The interference effects between external and internal flows are examined in the framework of the inviacid flow theory. These phenomena are connected mainly with flows around afterbodies. Subcritical exisymmetrical interacting flows are studied. The computation of both internal and external flows is carried out using a finite element method. The results make it possible to determine the shape of the jet using a pseudo-hodographic method, with an iterative procedure. The interference effects of a supersonic internal flow with subsonic or transonic external flows are considered. The aupersonic internal jet is computed using the method of characteristics. The coupling conditions between the internal and the external flows are taken into account, using an iterative procedure in a way similar to that proposed by Young, but extended to compressible external flows. A comparison with existing experimental results is pre-outed.

LOW SPEED INJECTION EFFECTS ON THE AERODYNAMIC PERFORMANCE AT TRANSONIC SPEED

Renzo Piva In AGARD Airframe/Propulsion Interference Mar. 1975 10 p. refs. Prepared jointly with Rome Univ. (For availability see N75-23485 18-02)

(Grant AF-AF08R-72-2167)

The problem concerning the possible reduction of the transonic drag for a high speed airplane was studied to enhance the serodynamic performance at low sititudes when the drag must be minimized. Attention was focused on decreasing the drag forces on the aft portion of the vahiole. An experimental investigation was conducted to determine the effect, on afterbody drag, of the injection of a small amount of air spilled from the propulsive system, having low stagnation pressure, in the rear of the model. The purpose of this injection was to avoid overexpansion of the flow and to increase the average pressure on the aft section. The main problem to be investigated is where the injection is most effective and the amount of air required to avoid downstream resitachment. Some results are presented, it was found that the required amount of air is relatively low, because of the high sensitivity of the interaction region to any small change in the flow regime Author

RESEARCH ABOUT EFFECTS OF EXTERNAL FLOW AND AIRCRAFT INSTALLATION CONDITIONS ON THRUST REVERSERS PERFORMANCES

J. M. Hardy and J. P. Carro. In AGARD. Airframe/Propulsion Interference Mar. 1975. 11 p. in FRENCH; ENGLISH summary (For availability see N75-23485. 16-02).

Development of thrust reversers is generally carried out in engine test cells without external flow. As thrust reversers deviate a significant smount of flow this modifies the serodynamic field surrounding an alroisft. Inversely, flight speed as well as sicraft installation conditions react on the operating characteristics of thrust reversers. This interaction is contingent on the thrust reversers design arrangement. The interaction mechanisms is analyzed using test data collected with two types of thrust reversers during an investigation carried out on the CONCORDE

afterbody. The differences in behavior existing between the reveisers are shown as revealed by tests carried out with no external flow, and with external flow in the O.N.E.R.A. wind tunnel installation. An investigation on interaction mechanisms is presented, bringing out a correlation parameter which makes it possible to extrapolate thrust reverser results obtained in static conditions for various running configurations. A balance of decaleration forces are analyzed, and the effects of flight Mach number on the reversers base pressure values are shown.

REVERSE THRUST EXPENIENCE ON THE CONCORDE

A C Willmer and R L Scotland In AGARD Airframe/Propulsion Interference Mer. 1975-15 p. refs (For availability see N75-23485-15-02)

Reverse thrust is used as a means of deceleration on many sircraft. Particul limitations to its use are set by the following sirframe/propulsion interference of hot gas ingestion, and aircraft handling. The reverse thrust force may also differ from that measured on a test bad due to interference. Model tests to determine these interference effects for the Concorde aircraft were carried out. The several test techniques used are described, the model results are compared with those inferred from tests on the pr. totype and production signaft.

REYNOLDS NUMBER EFFECTS ON FORE- AND AFTBODY PRESSURE DRAG

Felix Aulehia and Geert Besigk. In AGARD. Airframe/Propulsion Interfarence. Mar. 1975, 15 p. refs (For availability see N75-23485, 15-02).

As analysis of a wind tunnel investigation at Manh number 0.8 on a series of axisymmetric bodies showed as a main result that varying Raynolds number produces opposite changes in pressure drag on fore- and attbody, respectively, it is explained that this result could very well be caused by wind tunnel interference. As a consequence, to determine attbody drag correctly it will be required either to test in interference free wind tunnels or to take into account the companishing effects on the forebody. Furthermore, it is pointed out that modifications in attbody geometry affect forebody drag. Results from the commonly used affibody test rigs with forebodies fixed to the ground therefore need appropriate corrections. Finally, the sensitivity of drag components with respect to the location of split lines is discussed, it is shown that subdividing the boattail is not advisable from an accuracy point of view. THE SUBSONIC BASE DRAG OF CYLINDRICAL TWIN-JET AND SINGLE-JET AFTERBODIES

J. Reid, A. R. G. Mundell, and J. F. W. Crane. In AGARD Airframe/Propulsion Interference. Mar. 1975. 13 p. refs (For sysilability see: N75-23485 15-02)

The effect was studied of forebody and support interference on the base drag of cylindrical twin-jet afterbodies in wind tunnel tests at subscoild speeds. Two almost identical afterbodies were tested, one in a strong interference field and the other nearly free from interference. The results illustrate the importance of the effect and also serve to test two methods of correction Supplementary tests show that the base drag of a cylindrical twin-jet afterbody tends to be a slightly greater than that of the equivalent exisymmetric configuration. Finally, a method of correlation is described whereby the base drag of both twin-jet and single-jet models may be expressed in linear form. Author

ON SOME PROBLEMS ENCOUNTERED IN A THEORETICAL
STUDY OF THE EXTERNAL FLOW OVER A NOZZLE
CONFIGURATION IN TRANSONIC FLIGHT

T. H. Moulden, J. M. Wu, and D. J. Spring (Army Missile Command) in AGARD. Airframa/Propulsion interference. Mar. 1975, 12 p. refs. (For availability see N75-23485-15-02). (Contract DAAH01-74-C-0183).

Attention is drain to the lack of information, both experimental and theoretical, concerning the transonic flow over an engine configuration operating at various thrust levels. It is shown that the flow is of great complexity. In particular, when the free stream Mach number is just supersonic, it is found that the confluence between the jet and the external flow is still more nearly subsonic in nature. This observation implies that the usual theories for supersonic base flow are not applicable to this situation. Calculations from such a theory are presented and discussed in the light of experimental evidence. It is recommended that considerable effort be spent in developing theoretical tools based upon solutions to more exact equations and that more fundamental experiments be performed.

TWIN JET EXHAUST BYSTEM TEST TECHNIQUES

Ronald J. Glidewell and Arthur E. Fanning. In AGARD. Airframe/ Propulsion Interference. Mer. 1975. 11 p. refs. (For availability see N75-23485.15-02)

The problem of integrating sirframe and propulsion system requires that the various wind tunnel models, used in accomplishing the task, simulate as accurately us possible the internal and external flowfields that will be experienced on the dipplane itself. This is particularly true for those models which are tested to define inlet and exhaust system interactions with the airplane flowfield. Exact simulation is, however, prohibited by the limitations of wind tunnel test tenhniques. For the jet effects model, such limitations include the interference effects associated with the model support system, exhaust plume simulation and the use of inlet fairings in substitution for flowing inlets. Information from a variety of sources is used to assess the impact of these model limitations on the accuracy of afterbody performance measured on twin jet models.

N75-23601 * National Aeronautics and Space Administration. Langley Research Center. Langley Station. Va. AN EXPERIMENTAL STUDY OF JET EXHAUST SIMULA-TION

William B. Compton, III In AGARO Airframe/Propulsion Interference Mar. 1975 11 p. refs (For availability see N75-23485 14-02)

Avail NTIS CECL DIA

Afterbody drag predictions for jet sircraft are usually made experimentally with the jet exhaust flow simulated. The physical cas properties of the fluid used for the model jet exhaust can affect the accuracy of simulation of the airplane's jot exhaust plume. The effect of the accuracy of this simulation on afterbody drag was investigated by wind-tunnel tests with single engine model. In addition to unheated air as the exhaust gas, the decomposition products of three different concentrations of hydrogen peroxide were utilized. The air jet simulation consistently resulted in higher boattall drag than hydrogen peroxide simulation. The differences in drag for the various exhaust gases are attributed to different plume shapes and entrainment properties of the gases The largest differences in drag due to exhaust gas properties were obtained for the combination of high transonic Mach numbers and high boattall angles. For these conditions, the current data indicate that the use of air to simulate a nonafterburning turbojet exhaust can result in an increase in afterbody amounting to 20 percent of the nonafterburning turbojet value.

A MODEL TECHNIQUE FOR EXHAUST SYSTEM PERFORMANCE TESTING

T D. Coombes In AGARD Airframe/Propulsion Interference Mar. 1975 12 p. refs (For availability see N75-23485 15-02)

An accurate model technique is described that was developed to measure the sum of gross thrust and afterbody drag for nozzle systems with single or two co-axial streams. The rig uses air at ambient temperature and is designed to operate in the 9tr x 8ft transonic wind tunnel of the Aircraft Research Association Limited at Bedford Model test results are also presented to demonstrate the accuracy and repeatability of the rig and show the considerable progress that has been made in advancing the state of the art on exhaust systems for low specific thrust engines.

ISOLATING NOZZLE AFTERBODY INTERACTION PARAMETERS AND SIZE EFFECTS: A NEW APPROACH
S. C. Walker In AGARD Airframe/Propulsion Interference Mar 1975 8 p. rafs (For availability see N75-23485 15-02)

A flight test of the A-7E airplane is reported along with associated wind tunnel tests comprising approximately one hall of the long range program. The difficulty of controlling parameters in flight was overcome by flying into the data point while allowing only slight variations in ambient pressure. Wind tunnel tests were run with both hot and cold exhaust One model was a wingless body of revolution, the second was a geometric representation of the sirplane. The flight test demonstrated the practicability of parameter control testing, and showed applicability of stream thrust parameter to inflight engine performance evaluation. Wind tunnel data show trends and general levels comparable to flight, and have verified some areas in which development of corrections is necessary.

EXHAUST PLUME TEMPERATURE EFFECTS ON NOZZLE
AFTERBODY PERFORMANCE OVER THE TRANSONIC
MACH NUMBER RANGE

C. E. Robinson, M. D. High, and E. R. Thompson. In AGARD Airframe/Propulsion Interference. Mar. 1975. 16 p. refs. Sponsored in part by AEDC (For availability see N78-23485.15-02).

Results of an experimental research investigation on nozzle/afterbody drag are presented. Experimental afterbody (and boattail) drag coefficients and pressure distributions are discussed for an isolated, strut-mounted nozzle/afterbody model for the Mach number range from 0.6 to 1.5. The experimental data were obtained for the basic model with an air-cooled and a water-cooled ethylene/air combustor to provide hot-jet duplication as well as cold-jet simulation. The temperature of the nozzle exhaust gas was varied from 530 R (294.4 K) (burner-off) to approximately 2500 R (1888.9 K) for several nozzle pressure ratios from jet-off to those corresponding to a moderately under-expanded exhaust plume. The differences between the cold-jet and hot-jet results are significant, and adjusting the cold-jet pressure ratio to correct for the changes in the jet specific heat ratio with temperature will account for most of the differences observed.

THE INFLUENCE OF NACELLE AFTERBODY SHAPE ON AIRPLANE DRAG

Walter J. Rohling In AGARD Airframe/Propulsion Interference Mar. 1975 14 p. refs (Für availability see N75-23485 15-02)

A program to design and flight test quiet necesses suitable for installation on JT3D powered 707 sirplanes was conducted Design requirements for the quiet necesses and conducted Design requirements for the quiet necesses that the nacelle shall be flightworthy, flight weight, capable of being certificated to airworthiness standards, and appropriate to the aircraft type. The ordiss performance flight tests and the additional performance penalty due to the nonoptimum aft translating sleeve and fan nozzle configuration. An unfavorable angle-of-attack-sensitive interplay between the wing and necesses aft sleeve flow fields was found at all cruise Mach numbers. This penalty was the only significant item discovered during the flight test program which required correction to provide a viable retrofit nacelle configuration. The diagnostic performance flight tests, wind tunnel and exhaust system model tests are described that were conducted to define the required change and to obtain data on the cruise performance benefits that resulted from the change. Author

N75-23506* National Aeronautics and Space Administration Lewis Research Center, Cleveland, Ohio REYNOLDS NUMBER EFFECTS ON BOATTAIL DRAG OF EXHAUST NOZZLES FROM WIND TUNNEL AND FLIGHT TESTS

Fred A. Wilcox and Roger Chamberlin /n AGARD Airframe/ Propulsion Interference Mar. 1975 15 p refs (For svailability see N75-23485 15-02) Avail: NTIS CSCL 01A

A family of nacelle mounted high angle boattail nozzles was tested to investigate Reynolds number effects on drag. The nozzles were flown on a modified F-1068 and mounted on scale models of an F-106 in a wind tunnel. A 19- to 1-range of Raynolds number was covered as a result of the large size differences between models and by flying over a range of altitude. In flight the nozzles were mounted behind J-85 turbojet engines. Jet boundary simulators and a powered turbojet engine simulator were used on the wind tunnel models. Data were taken at Mach numbers of 0.6 and 0.9. Boattail drag was found to be affected.

by Reynolds number. The effect is a complex relationship dependent upon boundary layer thickness and nozzle boattail shape. As Reynolds number was increased from the lowest values obtained with scale models, boattail drag first increased to a maximum at the lowest flight Reynolds number and then decreased Author

N75-23507 Boeing Aerospace Co., Seattle, Wash ACCOUNTING OF AERODYNAMIC FORCES ON AIR-FRAME/PROPULSION SYSTEMS

Michael E. Brazier and William H. Ball. In AGARD Airframe / Propulsion Interference Mar. 1975. 15 p. refs (For availability see N75-23485 15-02)

Proper accounting, prediction, and measurement of propulsion system installation corrections are essential for the successful development of advanced military aircraft. The results are reported of recent studies which evaluate the methods used to predict, measure and integrate the serodynamic and propulsion forces within a force accounting procedure that provides maximum element visibility and accuracy, and is applicable throughout an entire sirplane development cycle. Improved analysis techniques are described which provide more comprehensive and accurate predictions of injet performance and nozzle/aftbody drag early in the preliminary design process. Inlet analysis techniques make use of standardized data maps for obtaining complete inlet performance characteristics. Nozzle/aftbody drag calculations are performed using a newly-developed truncated integral mean slope technique. Effects of strut interference, blockage, model split-line locations and other factors which introduce uncertainties into airframe/propulsion system data are presented.

ARPRAME/PROPULSION SYSTEM FLOW FIELD INTER-FERENCE AND THE EFFECT ON AIR INTAKE AND EXHAUST NOZZLE PERFORMANCE G. K. Hichey, L. E. Surber, and J. A. Laughrey. In AGARD Airframs/Propulsion Interference. Mar. 1975. 31 p. refs (For

availability see N75-23485 15-02)

The Interference between the sirframe flow field and the internal/external flow in the air intakes and exhaust nozzles of high performance tection aircraft is shown to have a significant impact on the performance and operating characteristics of these components, and hence on overall stroraft performance. The internal flow characteristics of an inlet system closely integrated with the airframe are strongly influenced by flow field nonuniformities generated by the sirframe forebody and wing, particularly at the higher angles of attack or yaw which modern tactical alroraft are capable of. Compatizons are made of the inlet ambient (capture plane) flow field, and pressure recovery, steady state and dynamic inlet distortion at the simulated engine compressor face for both integrated (side mounted and fuselage or wingshielded) and isolated inlet systems to quantitatively assess the sirframe interference affects. For the engine exhaust nozzles of closely integrated propulsion system/sirframe configurations, the major influence of the sirframe flow field is associated with the alteration of the viscous and inviscid external flow in the nozzle region, and its effect on external atthody/nozzle drag. A detailed discussion, supported by experimental data, shows the effects on airframe aftbody/nozzle pressure distributions and nozzle installed performance with respect to twin jet interference, wing flow, sincreft tail/control surfaces, interfairings and free stream How conditions

DETAILED EXPERIMENTAL AND THEORETICAL ANALYSIS OF THE AERODYNAMIC INTERFERENCE BETWEEN LIFTING JETS AND THE FUSELAGE AND WING

G Schulz and G. Viehwager In AGARD Airframe/Propulsion Interference Mar. 1975-13 p refs (For availability see N75-23485 15-02)

An aircraft model of simple shape for pressure distribution measurements is used, which allows the variation of all main geometrical parameters. The jots reach Mach number 1. Measurements of the velocity directional flow field are added. The pressure distributions as well as the flow directional field allow the physical interpretation of the several aerodynamic effects. By integration of the pressure field, the forces and moments caused by the jets are obtained. The integration of the directional field leads to the stream lines of the complicated field of cross blown jets. Theoretical momentum considerations enable the calculation of the jet path and lead to transcalculation rules for flow directional fields (downwash) from one dynamic pressure ratio to another Author

N75-23510 Deutsche Forschungs- und Versuchsanstalt führ Luft- und Raumfahrt, Brunswick (West Germany) PREDICTION OF THE OPTIMUM LOCATION OF A NACELLE SHAPED BODY ON THE WING OF A WING-BODY CONFIGURATION BY INVISCID FLOW ANALYSIS

S. R. Ahmed In AGARD Airframe/Propulsion Interference 1975 12 p refs (For availability see N75-23485 15-02)

Some results of a basic study are presented which aims at the prediction of optimum location of a pylon-mounted engine nacelle on the wing of a wing-body configuration with the help of inviscid flow analysis. The options considered are the underwing and overwing positions of the nacelle. Varied parameters are its spanwise and chordwise location along the wing. The criterion for the choice of the optimum location is the minimum possible induced drag of the wing-body-pylon-nacelle configuration. The theoretical calculation of the inviscid flow is done by the so-called 'panel method'. Feasibility of these predictions for subcritical flow is checked on the basis of extensive pressure and force messurements in a wind tunnel.

N75-23511 Vereinigte Flugtechnische Werke-Fokker G.m.b.H., Bremen (West Germany)

AIRFRAME: ENGINE INTERACTION FOR ENGINE CONFIGURATIONS MOUNTED ABOVE THE WING. PART 1: INTERFERENCE BETWEEN WING AND INTAKE

G. Krenz In AGARD Airframe/Propulsion Interference Mar 1975 32 p refs (For availability see N75-23485 15-02)

Advanced technology of airframe-propulsion-integration confirm the feasibility for over-the-wing engine installation of transport aircraft. Basic areas of interaction between wing and engine flows are described together with specific investigations associated with fore and aft engine locations. For the aft location, W/T results are presented with flight test data including stall and high speed flight characteristics. Further, low speed tunnel investigations of sircraft configurations with engine intakes well in front of wing L.E., result in increasing lift as well as improving the lift/dray ratio during T/O and landing. A theoretical approach was conducted, using the well established panel method, and comparison of theoretical and experimental pressure distributions proved well for spauling of one nozzle diameter between the wing and nozzle-jet sheet.

AIRFRAME: ENGINE INTERACTION FOR ENGINE CONFIGURATIONS MOUNTED ABOVE THE WING. PART 2: ENGINE JET SIMULATION PROBLEMS IN WIND TUNNEL YESTS

B Ewald In AGARD Airframe/Propulsion Interference 1975 17 p refs (For availability see N75-23485 15-02)

A test technique developed for the VFW-Fokker low speed wind tunnel is presented. In this technique the aliframe model is mounted to the external machanical balance (wire suspension). The engine pod is mounted separately on a tell sting suspension system. Due to the design of this tail sting system its angle of attack axis of rotation coincides with the corresponding axis of the external balance. So separate mounting of airframe and engine with very small gaps is possible. The sir is fed to the engine pod with high pressure (up to 20 atmospheres). This pressure is decreased to the required nozzle exit pressure ratio by perforated plates very close to the nozzle exit. Calibration results of this nozzle arrangement are given. Typical test results (force measurements, wing pressure distribution) are presented for several engine locations lover-wing, on-wing, under-wing)

AERODYNAMIC ASPECTS AND OPTIMISATION OF THRUST REVERSER SYSTEMS

Kurt Lotter and Wolfgang Kurz In AGARD Airframe/Propulation Interference Mar. 1975 22 p ref (For availability see N75-23485 15-02)

The present generation of commercial aircraft and future advanced military aircraft require thrust reversal for reduction of landing distances, especially for wet or loy runways. The various design and integration features for jet deflection are summarized, and the requirements and problem areas discussed under special consideration of a target type reverser system. The important engine/aliframe interference problems and serodynamic espects associated with thrust reversal are considered. Parametric investigation of thrust reverser geometry on efficiency, reingestion structure heating and longitudinal stability during ground roll is presented Results are based on an intensive wind tunnel test program using various types of scale models with cold and hot jets, intake suction and fixed and moving ground simulation Emphasis is given to the overall optimization of often conflicting requirements from parameters like for example thrust reverser performance and reingestion. The essential influence of appropriate thrust reverser operation and landing techniques at or shortly before touch-down on landing distance is shown

Structures Dept CALCULATION METHODS FOR THE FLUTTER OF AIMCRAFT WINGS AND EXTERNAL STORES T Nihlett and J C A Baldook In AGARD Specialists Meeting

on Wing-With Stores Flutter Apr 1975 7 p refs (For availability see N75-28011 19-02)

Theoretical work at RAE on the wing-with-stores problem is reported which was in the fields of structural representation. the solution of the flutter equations and the prediction of flutter characteristics from structural properties. The subjects covered are: (1) a comparison of the normal modes calculated for a wing-with-stores from some of the normal modes of the bare wing and discrete-load modes with those calculated from the full flexibility matrix; (2) the basis of a computer program which traces the loci of constant flutter speeds when two structural parameters vary; and (3) the interpretation of the loci of constant flutter speed in terms of model shapes and frequencies with the object of assessing the most critical store combinations

FLUTTER OF WINGS EQUIPPED WITH LANGE ENGINES IN POD

H. Destuynder In AGARD Specialists Meeting on Wing-With-Stores Flutter Apr 1976 12 p rafe in FRENCH, ENGLISH summary (For evailability see N75-28011 19-02)

Calculations and measurements of unsteady aerodynamic forces performed in subsonic flow on a model equipped with an engine in pod showed that the interference between engine and wing remains nepligible. It was also shown that the aerodynamic forces induced on the engine itself by its own oscillation are important and give a significant contribution to the generalized forces. Account was taken of these two remarks and the aerodynamic forces were calculated separately on the engine which was assimilated to a thin walled cylinder with internal and external flow in the axial direction. An application to a flutter case shows the importance of the contribution of the forces on the engine. A good agreement was obtained between theory and experiment at Mach number M - 0.80

N75-28015 National Aerospace Lab , Amsterdam (Netherlands) CALCULATION OF AERODYNAMIC LOADS ON OSCILLAT ING WING/STORE COMBINATIONS IN SUBSONIC FLOW

B Bennekers, R Roos, and R J Zwaan In AGARD Specialists Meeting on Wing With-Stores Flutter Apr 1975 13 p refs (For availability and N75-28011 19-02)

A method for the calculation of aerodynamic loads on

wing store configurations oscillating in subsonic flow is presented In this method the linearized equation for subsonic compressible flow is transformed into two sets of integral equations for the steady and a superimposed unsteady flow field. The wing loads are represented by dipole distributions (wing thickness is neglected) and the store loads by source distribituons. Discretizing these distributions into lifting lines and source panels of constant strength results into a set of algebraic equations. These are solved for the unknown distributions by forcing the flow to be tangential to the surfaces of the oscillating wings and bodies in a set of control points. The solution enables the calculation of pressure distributions on the wings and stores and of generalized serodynamic coefficients. Calculated results are presented and compared with experiments.

N75-28016 National Aerospace Lab , Amsterdam (Netherlands) ANALYSIS OF MEASURED AERODYNAMIC LOADS ON AN OSCILLATING WING-STORE COMBINATION IN SUBSONIC FLOW

L. Henirle. In AGARD. Specialists Meeting on Wing-With-Stores Flutter Apr 1975 15 p refs (For evallability see N75-28011 19-02)

An analysis is given of serodynamic loads measured with an oscillating wind tunnel model representing a wing with a tip tank and a removable pylon with store. Attention is paid to the interference effects on the wing load and to the pylon store load in low and high subsonic flow.

A PARAMETRIC STUDY OF WING STORE FLUTTER

L. Chesta In AGARD Specialists Meeting on Wing-With-Stores Flutter Apr. 1975 12 p refs (For availability see N75-28011 19-02)

The influence of different parameters on the flutter of wings with stores was studied in more than 3000 wind tunnel configurations. The parameters studied include store mass, store radius of inertia, store c.g., pylon pitch stiffness, and wing sweep angle. Results indicate. (1) Futter is indicaed by the coupling of the wing fundamental bending and the store pitch modes (2) Flutter spend decreases with increasing store radius of mertia until the frequency of the store pitch mode is higher than that of the fundamental lending (3) For all sweep angles, the forward c.g. shifting produces a slight reduction of the minimum flutter

N75-28019 Grumman Antospace Corp., Bothpage, N.Y. RECENT OBSERVATIONS ON EXTERNAL STORE FLUT. TER

Eugene F Baird and William B Clark In AGARD Specialists Moeting on Wing With-Storus Flutter Apr 1975 8 p refs (For availability see N75-28011 19-02)

The problem of wing flutter with external stores is dis-cussed in terms of flutter prevention when designing aircraft. General guidelines for the optimum arrangement of external stores on wings are given, and the mission-loading requirements for a new arroraft are considered. Other topics discussed include, pylons, flutter model tests, ground vibration tests, and flight flutter

N75-29020 Air Force Flight Dynamics Lab. Wright-Patterson

AFB. Ohio Recent analysis methods for Wing Store Flut TER

Walter J. Mykytow. In AGARD. Specialists Meeting on Wing With Stores Flutter Apr 1975 15 p refs (For availability 566 N75-28011 19-02)

A summary of a brief review for some of the literature on the practical aspects of wing-store flutter prediction and prevention. Brief comments are given on the advantages and disadvantages of various aspects of analytical and test procedures. Descriptions of improved analytical procedures developed for the United States Air Force is then given. Two methods are described in some detail and the results of the investigators are outlined. One is a rapid special purpose wing-store flutter analysis program called FACES It has data storage and retrieval capas, ands which together with a diagnostic and interpolation/extrapolation procedure estimate the flutter speed of new, similar stores. The system can be coupled to a cathode ray tube to increase man/machine interaction and reduce decision times. The other analysis method described is based on the perturbation approach. Computation times can be reduced 90% by using the previously available data. The method products good results when the mass or stiffness changes are small so that in turn, eigenvalue and eigenvector changes are small. A graph of flutter speed versus Important parameters can be produced in one minute on a modern Author

MATHEMATICAL MODELING AND RESPONSE EVALUA-TION FOR THE FLUCTUATING PRESSURES OF AIRCRAFT BUFFETING

John C. Houbolt (Aeron. Res. Assoc. of Princeton, Inc., N. J.) Jul. 1975–14 p

(AGARO-R-830) Avail NTIS HC \$3.25

The mathematical modeling used to describe the pressure fluctuations in various turbulent flow problems is reviewed; ettention in focused mainly on statistical description, such as are involved in power spectral approaches. These models were used as building blocks to synthesize a mathematical model describing the turbulent pressure fluctuations during buffeting of an airplane wing. Means for evaluating the dynamic response of the structure due to the buffeting forces were developed. An example treatment shows that the dynamic response may be an appreciable perrent of an associated reference static defication, it is recommended that a series of controlled buffet tests be read to check on the validity of the equations, and to establish their parameters.

FORCE MEASUREMENTS IN SHORT DURATION HYPER-SONIC FACILITIES

Leonard Berustein (Cueen Mery Coll.) and R. C. Pankhurst, ed Nov. 1975, 224 p. refs.

(AGARD-AG-214, AGARDograph-214) Avail NTIS HC \$7.75

Attention is drawn to the principle whereby the aerodynamic forces on a model in a wind tuniel are determined by measuring the reactions to them. The discussion is based upon a division of such reactions into two basic classes, depending on the restraints imposed. Where no restraints exist, the model flies freely and the forces may be inferred from the accelerations, either measured directly or derived from displacement vs. time data. When the model is supported, the forces are determined from measurements of the mechanical strains induced in suitably designed supports. Hybrid techniques, where these extreme cases of no restraint or nearly complete restraint comor be assumed, are also discussed. A detailed discussion of transitucer sensing elements and their incorporation into measuring systems is given. Some particular systems are also described. For individual titles, see N76-16020 through N76-18022.

Two dimensional and three dimensional laminar and turbulent separation phenomena in subsonic transonic, and supersonic flows are reported. For individual titles, see N78-17031 through N76-17070

N76-17031 Deutsche Forschungs- und Versuchsensteit füer Luft- und Raumfahrt, Goottingen (West Germany) AN ACCOUNT OF THE SCIENTIFIC LIFE OF LUDWIG PRANDTL

H. Schlichting In AGARD Flow Separation Nov. 1975 32 p. refs (For availability see N76-17030 08-02)

After an introduction on Prandtl's professional career the following are dealt with in Part I. Boundary layer theory, wing theory at subsonic and supersonic speeds, theory of stability of

laminar flow. Furthermore, in this section the following problems are touched on briefly. Fully developed turbulent flow with application to boundary layers, pipe flow and meteorology. Prandtl's contributions to development of wind tunnel techniques are also mentioned. In Part II some remarks are made on the large number of doctoral theses which have been supervised by Prandtl.

LAMINAR SEPARATION AT A TRAILING EDGE

Jean-Pierre Guiraud and Rene Schmitt. In AGARD. Flow Separation. Nov. 1975. 5 p. refs (For availability see N76-17030. DR.02).

A model of inciplent separation is provided for the trailing edge of a thin wing in incompressible very high Reynolds number flow. The model of separated flow, with a Ismalli recirculation zone, of streamwise length, is consistent with a matched asymptotic expansion scheme of solution of the Navier-Stokes equations in the vicinity of the trailing edge. The structure of the flow involves a triple deck of Sytchev's type very close to separation, embedded in another triple deck, of Stewartsons' type, which is relevant to the overall separated flow. Ignoring angle of attack effects, the flow depends on two constants, the value of vorticity in the recirculation zone and the precise position of separation, which is known already as far as order of magnitude is coherned.

LAMINAR SEPARATION: A LOCAL ASYMPTOTIC FLOW DESCRIPTION FOR CONSTANT PRESSURE DOWN-STREAM

A. F. Messiter In AGARD Flow Separation Nov. 1975 10 p refs (For availability see N76-17030 08-02) (Contract DAHC04-68-C-0033)

A theoretical model is proposed for the description of two dimensional, steady, incompressible, laminar boundary layer flow near a separation point. It is assumed that the pressure just downstream of separation is approximately constant, and asymptotic solutions are then sought for large Reynolds number and small distance. The first two terms of the complex perturbation velocity in the external flow are shown to imply a pressure gradient upstream which is generally favorable, and adverse only for a short distance. This representation is no longer valid in a small neighborhood of the separation point where an interaction of the boundary layer with the external flow must be taken into account. Solutions are obtained for the boundary layer just upstream and, with an additional assumption, for the region of backflow just downstream of this region. A brief review and extension are also given for an asymptotic model of the complete wake behind a circular cylinder, with the assumption of nonzero drag at infinite leynolds number

N76-17034 Ruhr Univ. Bochum (West Germany)
DEPENDENCE OF LAMINAR SEPARATION ON HIGHER
ORDER BOUNDARY LAYER EFFECTS DUE TO TRANSVERSE CURYATURE, DISPLACEMENT, VELOCITY SLIP
AND TEMPE TATURE JUMP

A. Wehrum In AGARD Flow Separation Nov. 1975 12 p refs (For availability see N76-17030 08-02)

The laminer compressible higher order boundary layer along a clicular cylinder in an axial parallel supersonic flow is studied according to the method of matched asymptotic expansions. A weak constant mass flow is injected into the boundary layer through the surface of the cylinder. As a consequence of the homogeneous mass injection the first order boundary layer solution aiready leads to separation of the boundary layer within a finite distance from the leading edge. In a second order theory the Influence of higher order boundary layer effects, such as transverse curvature, displacement, velocity slip and temperature jump, on the wall shear stress and the location of the separation point is studied. As numerical results show, transverse curvature and low density effects due to velocity clip and remperature jump at the wall increase the wall shear stress and therefore lead to a downstream shifting of the separation point. Displacement effect increases the wall shear stress near the leading edge.

EVALUATION OF SEVERAL APPROXIMATE MODELS FOR LAMINAR INCOMPRESSIBLE SEPARATION BY COMPAR-ISON WITH COMPLETE NAVIER-STOKES SOLUTIONS

K. N. Ghia, U. Ghia, and W. A. Teach (GE, Co., Evendale, Ohio)

In AGARD Flow Separation Nov 1975 15 p refs (For availability see N76-17030 08-02) (Grant NSF GK-35514)

Several approximate mathematical models have been analyzed for studying laminar separation for incompressible flow, for which the Navier-Stokes equations comprise an exact mathematical model. Two model flow configurations have been used. The first configuration considered consists of the flow in the boundary layer on a two dimensional semi-infinite slab with a vertical leading face and shoulders, with verying degree of bluntness, forming an external corner on the body. The second flow configuration represents a class of two dimensional bodies with an internal corner and a more pronounced separation region, this configuration is used for only one approximate models of an Results obtained with the various approximate models are evaluated by comparison with the corresponding Navier-Stokes solutions. All the models considered lead to improved results as the Reynolds number is increased.

NUMERICAL INVESTIGATION OF REGULAR LAMINAR BOUNDARY LAYER SEPARATION

H. P. Horton In AGARD Flow Separation Nov. 1975 12 p refs (For availability see N76-17030 08-02)

An accurate numerical procedure of the differential difference type for the solution of the Incompressible laminar boundary layer equations is presented. The procedure is applicable to both direct problems, in which the pressure distribution is prescribed, and inverse problems of the type in which the wall shear is prescribed. Some examples computed by this procedure show that, by prescribing the wall shear to be regular in the vicinity of separation, the usual singularity at separation is avoided. Results are also presented in which downstream marching with prescribed wall shear has been continued to considerable distances beyond separation, including an example in which both requier separation and re-attachment occur. In other cases no solution to the inverse problem can be found beyond a short distance after separation, but by smoothly joining a prescribed pressure distribution to that delculated in the inverse problem upstream, it has been found possible to continue the computation as a direct problem. Questions of stability and uniqueness of the solutions are discussed.

FINITE DIFFERENCE SOLUTIONS FOR SUPERSONIC SEPARATED FLOWS

M. J. Werle, A. Polek, V. N. Vatse, and S. D. Bertke *In* AGARD Flow Separation Nov. 1975 12 p refs (For availability see N76-17030 08-02)

(Contracts F33615-73-C-4014; N00019-73-C-0223; N60921-74-C-0203)

Laminar and turbulent separation bubbles are addressed for a wide range of geometries using an implicit finite difference technique to solve the interacting boundary layer equations. Solutions are presented for laminar compression ramps at $M \sim 4$ and 8, wall temperature ranges of 0.2 to 1.0 and angles of sweep (yaw) relative to the mainstream of up to 60 deg. In addition, solutions for laminar flow over wavy walls with multiple separation bubbles are given here for $M \sim 3$ Application of the approach to turbulent separated flows shead of a compression ramp at $M \sim 3$ is also considered. SEPARATION BUBBLE PRODUCED BY A SHALLOW DEPRESSION IN A WALL UNDER LAMINAR SUPERSONIC FLOW CONDITIONS (BULBE DE DECOLLEMENT PRODUIT PAR UNE FAIBLE DEPRESSION DE PAROI EN ECOULEMENT LAMINAIRE SUPERSONIQUE)

E. Prunet-Foch, F. Legay-Desexquelles, and G. B. Diep *in* AGARD Flow Separation Nov. 1975 9 p. refs. in FRENCH; ENGLISH summary (For availability see N78-17030 08-02)

In supersonic flow, a shallow deformation on a flat plate induces a small separated bubble in the boundary layer. In order to predict this laminar separation and restrechment process including heat transfer phenomens at the wall, a theoretical study was built up, using Dorodnitsyn integral's method as well as expressions suggested by Nielsen for the velocity and temperature profiles. Thereby the calculation can be carried out up to the reattachment point. Simultaneously experiments were made in a wind tunnel. Experimental and predicted results are in good agreement.

ASYMPTOTIC THEORY OF SEPARATION AND REATTACH-MENT OF A LAMINAR BOUNDARY LAYER ON A COM-PRESSION RAMP

Odus R. Burggraf In AGARD Flow Separation Nov. 1975 9 p. refs (For availability see N76-17030 08-02) (Contract N00014-07-A-0232-0014)

Laminar boundary layer separation and reattachment is here considered for adiabatic flow over a compression ramp with supersonic mainstream For large ramp angle, calculations based on the Stewartson-Williams triple dack theory show that the regions of separation and reattachment become distinct, with an intervening (plateau) region of nearly constant pressure. The mathematical description of each of these distinct regions is given, and simple formulas derived for a number of quantities of interest, including the plateau pressure, conditions at separation and reattachment, and the geometry of the separated region. Detailed comparisons of the theoretical results with available experimental data show favorable agreement.

N76-17040 Technische Hogeschool, Delft (Netherlands).
ON THE CALGULATION OF LAMINAR BEPARATION BUSBLES IN TWO-DIMENSIONAL INCOMPRESSIBLE FLOW

J. L. Vaningen In AGARD Flow Separation Nov. 1975 16 prefs (For availability see N76-17030 08-02)

A new laminer boundary layer calculation method is presented which combines the simplicity of Thwaites' method for the prediction of the momentum loss thickness with the accuracy of Stratford's two layer method for the prediction of the position of laminar separation. Calculated boundary layer characteristics for arbitrarily prescribed pressure distributions in general show a singular behavior at separation. It is shown that a real separating flow tends to adjust itself in such a way that the resulting pressure distribution prevents singular behavior of the boundary layer. An earlier method for the prediction of transition in attached boundary layers, based on linear stability theory, is extended to the case of separated flows. Two methods are discussed which might be used to predict whether restachment of the turbulent shear layer will occur. Finally some results are discussed wind tunnel experiments on the FX 66-S-196-V1 Wortmann airfoil, and on a circular cylinder with a tapered tail.

TURBULENT BEPARATION IN TWO-DIMENSIONAL FLOW [DECOLLEMENT TURBULENT EN ECOULEMENT BIDIMEN-SIONNEL]

Maurice Sirielx In AGARD Flow Separation Nov. 1875, 27 p refs. In FRENCH; ENGLISH summery (For availability see N78-17030 08-02)

The general features of separated turbulent flow regions are defined and in particular a discussion is made on the physical reality of strictly two dimensional turbulent flows. The three fundamental problems which occur in the detailed experimental analysis of a separated zone, i.e. separation, reattachment and coupling, are considered successively and the main factors of influence which rule these phenomena according to the subsonic transonic-supersonic nature of the flow are presented. Lastly, a rapid review of the methods of prediction currently available is made.

N76-17042 Queen Mary Coll., London (England).
MEASUREMENTS IN SEPARATING TWO DIMENSIONAL
TURBULENT BOUNDARY LAYERS

J. Chu and A. D. Young In AGARD Flow Separation Nov. 1975 12 p. refs. Sponsored by Min. of Defence (For availability see N76-17030 08-02)

Two different types of pressure distribution resulting in separation were induced in the flow over a flat plate zero incidence. Measurements were made of velocity distributions, skin friction, turbulence components and shear stress distributions at various stations both prior to and just after separation. The results have been compared with the predictions of various theories. Of these only those of Bradshaw and of Kuhn and Nielsen showed good agreement for integral quantities with the measurements right up to the separation point, the predictions of the remaining methods tended to depart radioally from the measurements some little distance shead of separation. Significant differences were found, however, between the measured shear stress distributions near separation and the predictions of Bradshaw's method, these

differences indicate where improvements to the method may be made. With certain important provisos the methods of Stratford and Townsend for predicting the separation position are shown to be fairly reliable.

CHARACTERISTICS OF A SEPARATING INCOMPRESSIBLE TURBULENT BOUNDARY LAYER

Roger L. Simpson In AGARD Flow Separation Nov 1975 14 p. refs (For availability see N78-17030-08-02) (Grante DA-ARO(D)-31-124-72-G31, UAHCO4-74-G-0024, DAHC04-75-G-0051)

Laser and hot film phemometer measurements upstream and downstream of the separation zone are presented for a nominally two dimensional incompressible turbulent boundary layer for an airfoil type flow. The directionally sensitive laser anemometer measurements indicate that the location of intermittent separation as defined by Sandborn is the proper location of where the flow first deflects from the wall to relieve the imposed pressure gradient. Upstream of separation the correlations of Perry and Schoffield for mean velocity profiles age supported within the uncertainty of the data. The separated flow field shows some profile similarity for all measured quantities. The normal stress terms in the momentum and turbulence energy equations are shown to be important near separation and cannot be neglected for the close prediction of the separation location.

THE PREVENTION OF SEPARATION BY BLOWING IN TWO-DIMENSIONAL FLOW

B. G. Newman and H. P. A. H. Irwin (Natt Res. Council of Can.) In AGARD Flow Separation Nov 1975 13 p refs (For evailability see N76-17030 08-02)

Two methods have been developed for calculating the jet momentum required to prevent the separation of the two dimensional incompressible turbulent boundary layer in adverse pressure gradients. The first was a strip integral method for plane walfs, the shear stress at each limit being based on measurements in self preserving wall jets. The second is an extension of differential methods which uses four model equations for the individual Reynolds stresses and one equation for the rate of turbulence dissipation. In general, the differential method is more accurate particularly when the outer wake is large. However, as used, this method required more input data and was about three times more expensive to run. The integral method is therefore still useful and is not limited to low quireture.

THE ANALYSIS OF FLOW FIELDS WITH SEPARATION BY NUMERICAL MATCHING

G. W. Brune, P. E. Rubbert, and C. K. Forester. In AGARD Flow Separation. Nov. 1975. 8 P. refs. (For availability see N76-17030-08-02)

(Contract F33615-73-C-3037)

A computing method is reported for flow fields characterized by the presence of viscous, separated regions interacting strongly with a surrounding inviscid flow. The procedure is to divide the flow field into several regions, each dominated by a particular type of fluid physics, and to analyze each region by using the numerical solution technique that is computationally optimum for the dominant type of flow. The paper specifically addresses the problem of matching a numerical solution of the Navier-Stokes equations for a region containing separated flow with another numerical solution appropriate for an adjacent region of inviscid flow A key feature of the method presented is the placement of the matching boundary in space occupied by purely invistid flow and remote from local areas of strong viscous/inviscid interactions. A detailed study and numerical substantiation of the method are presented for axisymmetric flow over an allipsoid of revolution with laminar separation.

EXPERIMENTAL AND THEORETICAL INVESTIGATIONS OF TWO-DIMENSIONAL REATTACHMENT IN TURBULENT INCOMPRESSIBLE FLOW [ETUDE EXPERIMENTALE ET THEORIQUE DU RECOLLEMENT BIDIMENSIONNEL TURBULENT INCOMPRESSIBLE]

Jean-Claude LeBalleur and Jean Mirande In AGARD Flow

Separation Nov 1975 13 p refs in FRENCH, ENGLISH summary (For availability see N76-17030 08-02)

Turbulent resttaching flow downstream of a backward facing step has been experimented using a two dimensional plane incompressible configuration, with possibility to induce favorable or adverse pressure gradients in the potential flow near resttachment. A whole calculation has been performed by obtaining nelf induced interaction in matching a well dissipative layer with an invisid and irrotational external flow. Except for weak viscous interaction regions, an inverse calculation process is used to avoid singularities following the Klinerberg's method for transonic servois. Wall pressure distribution than results of an integral boundary layer calculation, whose failure for strongly separated regions is easily overcome by substitution of an empirical pressure law.

G. R. Inger In AGARD Flow Separation Nov 1975 12 p. refs (For availability see N76-17030 08-02)

Two possible causes of the pronounced periodic spanwise disturbances that have been observed in nominally two dimensional or axi-symmetric reattaching laminar and turbulent separated flows are studied theoretically. Approximate analytical compressible small disturbance flow models for both a local vortex instability mechanism and the effect of a row of incoming streamline vortices are set up, solved and compared with available experimental data on surface disturbance pattern, pressure and heat transfer. The results on all counts confirm the predictions of the vortex instability model. It is also shown that Reynolds analogy does not apply to the disturbance skin friction and heat

N76-17048 Naval Surface Weapons Center, White Oak, Md. AN EXPERIMENTAL INVESTIGATION OF THE COMPRESSIBLE TURBULENT SOUNDARY LAYER SEPARATION INDUCED BY A CONTINUOUS FLOW COMPRESSION Robert L. P. Volsinet In AGARD Flow Separation Nov. 1975 11 p refs (For availability see N78-17030 08-02)

Flow field measurements of a compressible turbulent boundary layer on nozzle wall separation are presented. A continuous compression of the nozzle flow was imposed on the thick nozzle wall boundary layer to produce a streamwise pressure rise of sufficient strength to cause separation. The effects of Reynolds number on the separation phenomena are presented. For Reynolds numbers below 8. x 100,000 the separation length was found to increase with increasing Reynolds number, whereas for Reynolds numbers above 8. X 100,000 the reverse trend was observed. This reversal in the separation length versus Reynolds number trend was consistent with the reversal observed for inciplent separation versus Reynolds number correlations. Author

LAMINAR AND TURBULENT BOUNDARY LAYER SEPARA-TION AT SUPERSONIC AND HYPERSONIC SPEEDS John L. Stollery In AGARD Flow Separation Nov. 1975 11 p refs (For availability see N75-17030 08-02)

A number of theoretical and experimental investigations of shock boundary layer interaction are discussed. Both laminar and turbulent layers are considered, growing over two dimensional and axisymmetric bodies. For laminar flow a simplified version of the momentum integral method has been developed and used to predict incipient separation. A number of comparisons between experiment and theory for attached, incipient and well separated flows are included. For turbulent flow the three layer model proposed by Elistrom is shown to give good quantitative estimates of incipient separation and to explain the Reynolds number trend found experimentally. Since the turbulent boundary layer is more resistant to shock interference a very eimple attached flow theory is derived, which gives good predictions of both pressure and heat transfer at hypersonic speeds.

INCIPIENT SEPARATION OF A COMPRESSIBLE TURBULENT BOUNDARY LAYER

C. Appels and B. E. Richards in ACIARD Flow Separation Nov. 1975 12 p refs (For availability see N76-17030 08-02)

The separation of a turbulent boundary layer is studied that developed on nozzle walls induced by a compression corner at Mach numbers of 3.5 and 5.4 over a range of Raynolds numbers based on boundary layer thickness of 100,000 to 1 million. Careful application of liquid line and schlieren flow visualization techniques were used to detect separated length down to one tenth of boundary layer thickness. In this way separation was detected at lower flap angles than has been previously found at these conditions. The related finding of low indipient separation andie implies that flow reversal may occur initially only in the laminar sublayer, and this is confirmed by applying simple leminar correlations to this layer. This measured value of alpha sub i is found to be little dependent on Mach number and it is concluded that the large dependence of sigha sub i on this parameter found earlier is explained by each experiment detecting a different degree of onset of separation. The measured variation of siphs sub i with Reynolds number appears to follow the trend of development of the wake component in the undisturbed boundary layer.

N76-17051* National Aeronautics and Space Administration. Ames Research Center, Moffett Field, Calif. ON THE CALCULATION OF SUPERSONIC SEPARATING AND REATTACHING FLOWS

John D. Murphy, Lercy L. Presley, and William C. Rose In AGARD Flow Separation Nov. 1975 12 p refs (For availability see N76-17030 08-02) CSCL 01A

A method is developed for solving the laminar and turbulent compressible boundary layer equations for separating and reattaching flows. Results of this method are compared with experimental data for two laminar and three turbulent layer, shock wave interactions. Several Navier-Stokes solutions are obtained for each of the laminar boundary layer, shock wave interactions considered. Comparison of these solutions indicates a first order sensitivity in C sub f to the computational mesh selected in both the viscous and inviscid portions of the flow. Comparison of the present boundary layer solutions with the Navier-Stokes solutions and with data for a given Mach number indicates that as long as the separation bubble is small, the boundary layer approximation yields solutions whose accuracy is comparable to the Navier-Stokes solutions.

SUPERSONIC TURBULENT SEPARATED FLOWS UTILIZING THE NAVIER-SYOKES EQUATION

J. S. Shang and W. L. Hankey, Jr. In AGARD Flow Separation Nov. 1976 13 p. refs (For availability see N76-17030 08-02).

A modified eddy viscosity model is incorporated into the compressible Navier-Stokes equations and numerical solutions obtained for separated flows. The modification attempts to reproduce the response of a turbulent boundary layer to a severe pressure gradient by introducing a simple rate equation to account for the relaxation phenomenon. The system of equations is solved by MacCormack's time splitting explicit numerical scheme for a series of compression corner configurations. Computations are performed for ramp angle varying from 15 to 25 degrees at a Mach number of 2.96 and Reynolds number of 10 to the 7th power. An incident oblique shock impingement case is also computed at these same conditions and included for comparison with a ramp induced separation case. Calculations utilizing the modified eddy viscouity for the interacting turbulent flow compare very well with experimental measurements for the compression ramps, particularly, in the pradiction of the upstream pressure propagation and location of the separation and reattachment points. Good agreement is also attained between the measured and the calculated density profiles in the viscous inviscid Interaction region

N76-17083* National Aeronautics and Space Administration. Ames Research Center, Moffett Field, Calif. AN EXPERIMENTAL AND NUMERICAL INVESTIGATION OF SHOCK WAVE INDUCED TURBULENT BOUNDARY LAYER SEPARATION AT HYPERSONIC SPEEDS

J. G. Marvin, C. C. Horstman, M. W. Rubesin, T. J. Coukley, and M. I. Kussoy. In AGARD. Flow Superation. Nov. 1975 13 p. refs (For availability see N76-17030 08-02) CSCL 01A

A thoroughly documented experiment is reported that was specifically designed to test and guide computations of the interaction of an implinging shock wave with a turbulent boundary layer. Detailed mean flow field and surface data are presented

for two shock strengths which resulted in attached and separated flows, respectively. Numerical computations are used to illustrate the dependence of the computations on the particulars of the turbulence models. Models appropriate for zero pressure gradient flows predicted the overall features of the flow fields, but were deficient in predicting many of the details of the interaction regions. Improvements to the turbulence model parameters were sought through a combination of detailed data analysis and computer simulations which tested the sensitivity of the solutions to model parameter changes. Computer simulations using these improvements are presented and discussed

PREDICTION OF TURBULENT SEPARATED FLOW AT SUBSONIC AND TRANSONIC SPEEDS INCLUDING UNSTEADY EFFECTS

Gary D. Kuhn and Jack N. Nielsen. In AGARD. Flow Separation Nov. 1975 16 p refs (For availability see N76-17030 08-02)

An integral boundary layer method is extended to calculation of separated turbulent boundary layers in steady flow and to unsteady turbulent boundary layers. Separated boundary layers are calculated by treating the pressure as a dependent variable and prescribing the wall shear variation. The boundary layer method and a suitable potential flow method are used in an iterative procedure to produce a method for predicting the characteristics of separated flows. Good comparisons are shown between the theory and data for a separated turbulent boundary layer on the wall of a transonic wind tunnel. Analytical solutions developed from a small perturbation analysis indicate the method is valid for unsteady flow over a certain range of frequencies. Good comparisons were obtained between the linearized theory and results produced by a finite difference solution of the complete nonlinear unsteady boundary-layer equations. Examination of the nature of the integral equations in the vicinity of a point of zero Wall shear stress indicates that the shear stress gradient decreases approaching the point of zero shear.

VISCOUS INTERACTIONS WITH SEPARATION UNDER THANSONIC FLOW CONDITIONS [INTERACTION VIS-QUEUSE AVEC DECOLLEMENT EN ECOULEMENT TRANS-SONIQUE!

J. Delery, J. J. Chattot, and J. C. LeBalleur In AGARD Flow Separation Nov. 1975 13 p refs in FRENCH; ENGLISH summary (For availability see N76-17030 08-02)

Strong viscous interactions which are present in transpric flows past sirfolls give rise to an important thickening of the boundary layer with the frequent formation of a separated region. Under such conditions, the calculation of the flow must call upon rapid interaction theories whose application for the case of a turbulent boundary layer is examinated in conjunction with experimental analysis. A detailed analysis of the flow field has been made by using interferometry and a method of calculation similar to Klineberg's approach. The principle of this theory is to divide the flow into two domains: a weak interaction region where the pressure gradient is moderate, and a repid interaction region if separation is likely to occur.

N76-17066 Technische Hochschule, Aachen (West Germany) UNSTEADY SHOCK WAVE-BOUNDARY LAYER INTERAC-TION ON PROFILES IN TRANSONIC FLOW

Klaus Finke In AGARD Flow Separation Nov. 1975 11 prefs (For availability see N76-17030 08-02)

Many unsteady flows are characterized by the interaction of shock waves with separated boundary layers. In particular shock oscillations oncur on thick airfoils at high angles of attack and transonic free atream Mach numbers. Measurements were carried out in an intermittent indreft tunnel to study shock oscillations on various two dimensional wings. Alternating separation and attachment at the leading edge is the observed severest type of the unsteady flow conditions. For this case multispark interferograms show periodical oscillations of the circulation of the wing. accompanied by the same oscillation of the disculation in the opposite sense in the wake. Large periodical disturbances exist throughout the entire flow field with defined phase shifts. The primary source of the observed instability is the shock induced separation of the boundary layer on the profile.

N76-17057 Max-Planck-Institut fuer Stroemungsforschung. Goettingen (West Germany). SHOCK INDUCED FLOW OSCILLATIONS

G. E. A. Meier In AGARD Flow Separation, Nov. 1975, 9 p. refs (For availability see N76-17030 08-02)

The physical system consisting of a shock wave and the downstream separated flow causes oscillatory instabilities in three cases described here: transonic flow in a curved channel; flow over a symmetric profile at angle of attack; and flow in a Laval nozzie. The shock boundary layer interaction creates or displaces a separation bubble, thereby changing the flow field downstream of the shock root. This process usually strengthens the shock wave by increasing the back pressure. The shock wave then becomes unsteady, moving the separation point with it in an upstream direction, so that a self preserving instability occurs, thus reducing the flow velocity in the whole transonic field. By means of the later reattachment of the boundary layer, the entire flow is accelerated and tends to return to the initial condition. i.e., the process is cyclic. The length of the oscillation periods can be estimated.

N75-17058 National Aerospace Lab., Amsterdam (Netherlands) EXPERIMENT ON TRANSONIC SHOCK WAVE BOUNDARY LAYER INTERACTION

J. W. Kool In AGARD Flow Separation Nov. 1975 10 p

refs (For availability see N76-17030 08-02)

An experiment is described in which a normal shock interacts with a two dimensional turbulent boundary layer in an uniform flow with a Mach number of 1.4. The wall pressure distribution in the interaction region was measured and detailed pitot and static pressure surveys were made. The flow field was enalyzed and no supersonic tongue was found downstream of the shock The velocity profiles were integrated to obtain the integral properties whereas the skin friction was derived from Clauser plots. From the distribution of skin friction and the behavior of the integral properties it has been concluded that the boundary layer separated at the foot of the shock and restrached 4.5 undisturbed boundary layer thickness downstream of the separation point. The velocity profiles at the start of the interaction and downstream of the reattachment point correlate well with the logarithmic velocity distribution in the wall region.

N76-17069 Royal Aircraft Establishment, Fainborough (England). REVIEW OF SEPARATION IN STEADY, DIMENSIONAL FLOW

J. H. B. Smith In AGARD Flow Separation, Nov. 1975, 17 p.

refs (For availability see N76-17030 08-02)

An attempt is made to present a unified view which leads from a consideration of the structure of the problem and the role of modelling, through the partial solutions which have been found, to some illustrations of the application of three dimensional flow separation in aircraft design. Much of the work reported is only partially three dimensional, in the sense that boundary layers are calculated for fluws over cones or infinite sheared wings and that slender body theory is used to calculate the separated flow. These treatments reveal the limitations of some two dimensional concepts like resttachment and present an exciting range of problems and possibilities. Author

N76-17060* R and D Associates, Santa Monica, Calif. LAMINAR SEPARATION ON A BLUNTED CONE AT HIGH ANGLES OF ATTACK

Stephen C Lubard In AGARD Flow Separation Nov. 1975 11 p. refs (For availability see N76-17030 08-02)

(Contract NAS2-8113)

A new technique is reported for calculating the entire flow field on spherically blunted cones at high angles of attack and high laminar Reynolds numbers. An approximate system of parabolic equations obtained from the steady Navier-Stokes equations by assuming the viscous, streamwise derivative terms are small compared to the viscous normal and olroumferential derivatives is the basis of the calculations. These equations are valid for both the inviscid and viscous regions, including the circumferential separation zone that develops on the leeward side at high angles of attack. Two different methods are used to obtain the initial conditions for these equations at the sphere cone tangency plane. For small nose Reynolds numbers, an axisymmetric merged layer solution around a sphere is rotated to provide a three-dimensional initial plane of data. For large nose Reynolds numbers, the nose region is solved using an invisold, three dimensional time dependent solution combined with a boundary layer solution for the viscous flow. The computed flowfield including the leeward separation region is described and compared with data for a 7 deg half angle cone at 10 deg angle of attack, and a blunt 16 deg half angle cone at 15 deg angle of attack

CALGULATION OF THE THREE DIMENSIONAL LAMINAR BOUNDARY LAYER AROUND SOCIES OF REVOLUTION AT INCIDENCE AND WITH SEPARATION

Wolfgang Geibler In AGARD Flow Separation Nov. 1975 11 p. refs (For availability see N76-17030 08-02)

A numerical method is presented to calculate the three dimensional laminar incompressible boundary layer over bodies of revolution at incidence. The inviscid flow velocities used for the boundary condition at the outer edge of the boundary layer are determined numerically by a singularity method. The boundary layer calculation is carried out in a streamline coordinate system. The coordinates are fixed to the streamlines and equipotential lines of the inviscid flow. The boundary layer equations are integrated by an implicit finite difference method. Ar. a result of the numerical calculation process the velocity profiles in directions of streamlines and equipotential lines are known for each mesh point of the coordinate system, it is shown that this method can be used to determine the separation lines on the body surface.

THREE DIMENSIONAL SEPARATION OF AN INCOMPRESSIBLE TURBULENT BOUNDARY LAYER ON AN
INFINITE SWEPT WING

A. Elsenaar, B. VandenBerg, and J. P. F. Lindhout In AGARD Flow Separation Nov. 1975 15 p. refs (For availability see N76-17030 08-02)

A three dimensional boundary layer flow under infinite swept wing conditions is simulated. A description is given of the development of the boundary layer in a region of an adverse pressure gradient leading to increased cross flows and finally terminating in a three dimensional separation. Measurements are reported of the mean velocity profiles, the wall shear stress and the components of the Reynolds stress tensor. These measurements reveal a decreasing mixing length with increased gross flow and a substantial difference between the direction of the shear stress and the velonity gradient. After the separation line a region with an almost spanwise flow is observed. Calculations are presented of the boundary layer development with a finite difference method using semi-empirical shear stress relations based on the turbulent energy equation. This method falls to predict separation. When empirical modifications, based on the experimental results are introduced, the agreement improves. Close to separation, however, the calculations are very sensitive to the pressure distribution and this might be related to a Goldsteintype singularity at separation.

N76-17063* National Aeronautics and Space Administration Ames Research Center, Molfett Field, Colif. THREE DIMENSIONAL BOUNDARY LAYER SEPARATION IN SUPERSONIC FLOW

William D. Bachalo and Maurice Holt In AGARD Flow Separation Nov 1976 13 p. refs. Prepared in cooperation with Calif-Univ., Berkeley (For availability see N76-17030-08-02) CSCL 01A

An account is given of a detailed experimental investigation of three dimensional boundary layer separation in supersonic separation. In investigating three dimensional effects on supersonic separation, models were chosen which exhibited departures from two dimensional flow in the simplest way. The plane compression corner was replaced by a plate attached to a swept back wedge formed by two obliquely intersecting planes. Maintaining a constant tunnel Mach number of 2.5, surface pressure measurements were made on these models at static orifices spaced along the centerline and along three parallel lines. The flow parameters in the boundary layer and separated regions adjacent to the model surface were measured by traversing hot wire and pitot probes. The traverses were taken across the boundary layer and reversed flow regions in a direction normal to the body surface, they were made in several vertical planes, including the plane of symmetry.

N76-17064 Salford Univ. (England). Dept of Machanical Engineering PRESSURE RISE TO SEPARATION IN CYLINDRICALLY SYMMETRIC SHOCK WAVE, TURBULENT BOUNDARY LAYER INTERACTION

D. F. Myring In AGARD Flow Separation Nov 1975 14 p. refs (For availability see N76-17030-08-02)

Integral equations governing the three dimensional flow in a cylindrically symmetric shock wave turbulent boundary layer interaction are written in the form of momentum equations for directions normal to and aligned with the line of the shock, plus an entrainment equation. By neglecting the contributions of surface friction and mass entrainment, direct dependence on spatial derivatives is removed and solutions are obtained using the Mager cross flow profiles and power law profiles for the streamwise flow. Results are produced for angles of sweep greater than 45 deg which show good agreement with experimental measurements of pressure rise to separation. For smaller angles of sweep the theory suggests that the skin friction becomes vanishingly small at separation, which in turn suggests the need for a modified separation oriterion.

THE STRUCTURE OF THREE DIMENSIONAL SEPARATED FLOWS IN OBSTACLE, SOUNDARY LAYER INTERACTIONS

Raymond Sedney and Clarence W. Kitchens, Jr. // AGARD Flow Separation Nov. 1975. 15 p. refs (For availability seg. N76-17030 OB-02)

The turbulent boundary layer on the wall of a continuous supersonic wind tunnel is studied. Sizeable separated flow regions can be studied since the wall width is 35 cm and the boundary layer is typically 2.5 cm thick. The large scale of the experiment is required to resolve the fine details of the flow structure. The flow visualization techniques are discussed. The variation of primary separation distance is presented as a function of M. R. and obstacle dimensions. Some scaling laws that have been proposed are not supported by our results. The structure of the separated flow upstream of the obstacle changes with relatively small changes in R; the number of vortices varies from 5 to 4 to 2 as R changes. Data are presented for large and small protuberances, but the latter are emphasized.

R. H. Page and C. E. G. Przirembel. In AGARD. Flow Separation Nov. 1975 7 p. refs (For availability see N76-17030 08-02)

A cinematographic study utilizing high speed motion plature photography was carried out for a series of supersonic separated flow configurations. A two dimensional variable Mach number wind tunnel was used to produce flow fields about several sting supported models, including a sphere, a blunt body with a leading spike and a missile. Color Schlieren and shadowgraph techniques were the primary diagnostic tools used in these studies for some film sequences, these flow visualization techniques were anhanced by the addition of small particles. The chief results of these studies are presented in a 16mm color motion picture film. Excellent qualitative descriptions of various supersonic, separated flow fields have been obtained by viewing these high speed motion pictures on a reduced time scale or on a frame-by-frame basis.

THE THREE DIMENSIONAL SEPARATION OF A TUR-BULENT BOUNDARY LAYER BY A SKEWED SHOCK WAVE AND ITS CONTROL BY THE USE OF TANGENTIAL AIR INJECTION

David J. Peake and William J. Rainbird (Carleton Univ.) In AGARD Flow Separation Nov 1975 34 p refs (For evailability see N78-17030 08-02)

The three dimensional interaction of a skewed shock wave with a turbulent boundary layer, that is generated by a variable angle wedge standing normal to a flat test wall, has been systematically investigated at nominal mainstream Mach numbers of 2 and 4, up to and beyond shock strengths sufficient to cause incipient three dimensional separation. In the Mach number 2 flowfield, with wedge deflection angles of 8 and 11.5 deg. blowing air at Mach 3 was introduced upstream of the interaction and tangential to the wall. The objective was to control and remove the three dimensional separation. The jet excess momentum for this control situation was slightly more than the momentum deficit of the undisturbed boundary layer. In addition to the control of the maunitude of the blowing momentum, the direction of the wall jet could also be changed by rotating the line of the jet efflux. The optimum direction of blowing was found to be along a line somewhere between the deflected surface of the wedge and the line of the oblique shock wave.

N76-17069 Princeton Univ., N.J. AN EXPLORATORY OF A THREE DIMENSIONAL SHOCK WAVE BOUNDARY LAYER INTERACTION AT MACH 3 B. Oskam, J. E. Vas, and S. M. Bogdonoff In AGARD Flow Separation Nov. 1975 14 p refs (For availability see N75-17030

An exploratory experimental investigation has been carried out on the three dimensional flow fields caused by the interaction of oblique shock waves and a planar turbulent boundary layer The study was performed at a free stream Mach number of 2.95, a Reynolds number per inch of 1.6 x 106 and near adiabatic wall conditions. The interaction was studied on two experimental configurations having different initial boundary layer thicknesses Both surface measurements as well as complete flow field surveys were performed. The main contributions of the present investiontion are two experimentally derived flow field models for shock generator angles of 4 deg and 10 deg. Based upon both static pressure and surface flow patterns, as well as heat transfer data, the interaction region can be characterized as quasi-twodimensional along the shock direction in the region studied. A critical examination of the occurance of ordinary flow separation and its character was carried out. It was concluded that McCabe's criterion is not a sufficient condition to determine the onset of

STORE CONFIGURATIONS

Roger Destuynder In AGARD Comments on Transonic and Wing-Store Unsteady Aerodyn. Jan 1976 p 30-37 refs. in FRENCH: ENGLISH summery (For availability see N76-18059

Measurements are made at various Mach numbers on a semi-span model oscillating in pitch. Several kinds of stores. differing in size and position, were mounted. In each case, the characteristic values due to the store itsulf, those due to the interaction between wing and store, and lastly the values relative to the clean wing were measured. Calculations were performed in order to compare theory and experiment. Two methods were applied the first one, developed by ONERA, is a anmi-empirical method making use of Mach number fields, the other one, used by the NLR Amsterdam, is more complete as it determines directly the interaction between wing and store. introducing source and doublet distributions on the store, the pylon and the wing. In all cases, it appears that the main term is the interaction created by the store on the wing, which can enteri a variation of up to 15% of the lift coefficient. Author

TECHNICAL EVALUATION REPORT OF AGARD SPECIAL-ISTS MEETING ON WINGWITH STORES FLUTTER

Walter J Mykytow (AFFD1) Feb 1976 13 p. refs. Meeting held at Munich, 9 oct 1974 during 39th Meeting of Struct and Mater Panel

(AGARD AR 98. ISBN 92 835 1209 X) NUS HC \$3 50

The carnage of stores on wings significantly changes their dynamic characteristics and often adversely affects their flutter properties as a result of reduced wing frequencies and the introduction of critical frequency ratios together with inertia, clastic and aerodynamic coupling between loads. Adverse flutter characteristics and significantly lowered flutter appeals occur and these restrictions neverely constrain the speed - sitifude performance envelope that can be achieved by an aircraft. The variety of stores that can be carried on modern tactical sirplanes gonerates a need to accurately evaluate the literally thousands of possible store combinations which can be carried by such ancraft. Results are presented from a conference on information and procedures in use in the various NATO nations to solve the flutter problems associated with the narriage of external stores. on wings. Nine presentations were given and are summarized Recommendations concurring possible future efforts on the subject.

PREFACE TO FIGURES AND TABLES

William P. Rodden (La Canada, Calif.) In its A. Companson of Methods Used in Interfering Lifting Surface Theory Feb. 1978 p 13-25 rafs (For availability see N76-23163 14-02)

Data are compared from three different solutions of the lifting surface problem. The first task is the determination of the flow field, i.e., the velocity components in the field surrounding the oscillating wing. The second task is the palculation of the interference loading, i.e., lift and moment coefficients, on two surfaces induced by the motion of the forward surface. The third task is the calculation of the generalized forces resulting from the motions of the various components of an interfering wing-horizontal tail-fin configuration. The computation of each of these derived quantities from the solution of the basic litting surface problem is indicated below.

UNSTEADY ARRODYNAMIC PREDICTION METHODS APPLIED IN ARROSLASTICITY

B Laschka In AGARD Unsteady Aerodyn Mar 1976 31 p

refs (For availability see N76-24146 15-02)

A brief survey is given on the basic prediction methods in unsteady serodynamics needed in aeroelasticity. After an introductory outline of some of the most important seroelastic phenomena, some representative concepts applied to calculate unsteady serodynamic forces in subscrip and supersonic flow are described. Then, attention is drawn to areas which are not yet covered adequately by the presently existing theories. These sees comprise effects of gap geometry between fixed wing and control surfaces, of mean incidence about which a wing or control surface is oscillating, of wing thickness, of Reynolds number, etc Furthermore, some not yet published results related to interfering multiple lifting configurations are presented. These results include thrust calculations on oscillating landem wings in incompressible flow, wing induced unsteady tail loads and some downwash evaluations behind wings in supersonic flow

UNSTEADY PRESSURES DUE TO CONTROL SURFACE ROTATION AT LOW SUPERSONIC SPEEDS: COMPARISON BETWEEN THEORY AND EXPERIMENT

C. G. Lodge (British Afforaft Corp. Limited, Lanshire) and H Schmid (Messeradhmitt-Bolkow-Blohm GmbH, Munich) Sep 1978 21 p refs Presented at the 42d Meeting of the Structures and Miterials Panel, Ottawa, 5 Apr. 1976 (AGARD-R-647: ISBN-92-836-1223-5) Avail: NTIS

Most sircraft flutter problems have featured control surfaces, and it is necessary that unsteady serodynamic forces generated by their motions should be accurately predicted. Therefore theoretical and experimental studies were conducted on a planform with part span control surface oscillating in the control surface rotation mode at low supersonic Mach numbers. The results are presented and discussed. It is shown that these studies must be of a high accuracy so that the more critical aerodynamic confficients, such as hinge moment demping, are determined with confidence.

THREE-DIMENSIONAL FLOW CALCULATION FOR A TRANSONIC COMPRESSOR ROTOR

William T. Thompkins, Jr. and David A. Oliver. In AGARD Through Flow Calculations in Axial Turboniachinery. Oct. 1976. 18 p. refs. (For primary document see N77-12013-03-02). (Grant NGL-22-009-383).

Avail: NTIS HC A11/MF A01

A numerical calculation of the steady, inviscid, three dimensional flow in a isolated transonic compressor rotor has been completed using MacCormack's second order accurate time-marching scheme. This rotor has a tip Mach number of 1.2, an overall diameter of 2 feet, and inlet hub/tip ratio of 0.5. The computed rotor total pressure ratio is 1.82. Comparisons between the numerical solution, measurements of the intra-blade static density field obtained by gas fluorescence, and time resolved exit flow measurements showed that the inviscid computation accurately models transonic rotor aerodynamics and rotor blade pressure distributions in the upstream portions of the blade passages, the viscous effects influencing mainly the downstream flow.

THROUGH-FLOW CALCULATION PROCEDURES FOR APPLICATION TO MIGH SPEED LARGE TURBINES
H. J. A. Cox. In AGARD Through-Flow Calculations in Axial

Turbomachinery Oct. 1976 13 p. refs (For primary document see N77-12013 03-02)

Avail: NTIS HC A11/MF A01

Major difficulties arise in the evaluation of through-flow solutions relevant to conditions existing within the rear stages of large modern low pressure steam turbines. The highly loaded stage designs in which convergent-divergent profiles are used require computation procedures which can accurately allow for supersonic Mach numbers at both guide and runner blade outlet, high values of streamline slope in the meridional plane and varying quantities of mass flow tapped off between stages. The consequent effect of these conditions on turbine performance and various methods by which they can be incorporated into a streamline curvature computation process are discussed together with the use of steam thermodynamic data. Procedures which can be employed to obtain numerical stability and convergence in the computation process are suggested and further problems concerned with the evaluation of off-design solutions are briefly considered.

DESIGN OF TURBINE, USING DISTRIBUTED OR AVERAGE LOSSES; EFFECT OF BLOWING

D. K. Mukherjee In AGARD Through-Flow Calculations in Axial Turbomachinery Oct. 1976 14 p refs (For primary document see N77-12013 03-02)

Avail: NTIS HC A11/MF A01

The design of a multi-stage turbine begins with one dimensional calculations. Flow field computations which then follow are invaluable as they allow to determine velocity triangles at different radii and to design the blades. In these calculations, serodynamic losses and outlet angle deviations due to secondary and tip clearance flow, as well as the influence of coolant on the main stream expansion are taken into account.

Blade row performance paremeters, such as total-pressureloss coefficients and flow deviations, remain the weak assumptions in most of the otherwise sophisticated calculations of turbine flow conditions. Some of the areas are reviewed in which further efforts are needed. Since a turbine's performance ultimately depends on the detailed design of the baiding, the paper concentrates on this aspect of turbine design and analysis.

COMPARISON BETWEEN THE CALCULATED AND THE

EXPERIMENTAL RESULTS OF THE COMPRESSOR YEST

H. B. Weyer and R. Dunker In AGARD Through-Flow Calculations in Axial Turbomachinery Oct. 1976 26 p refs (For primary document see N77-12013 03-02)

Avail: NTIS HC A11/MF A01

For the calculation of the compressor's overall performance, one-dimensional techniques as well as dust flow and through-flow methods were used. No characteristic differences encounter from the various methods indicating that a severe effect of a more or less complete physical flow model does not exist. The deviations as far as observed with respect to the experiments are primarily due to the inaccuracy of the flow loss and flow turning predictions, particularly at off-design operating conditions. The duct-flow and through-flow calculation techniques were mainly utilized to compute in detail the compressor internal flow. Streamline curvature, matrix, and finite element methods thereby served as numerical procedures to resolve the flow equations. Concerning the flow parameters calculated outside of the blade rows no evident superiority was observed for any method even for the through-flow techniques although their physical background seems to be more accomplished taking for instance into account the effects of blade thickness, blade turning, a s.o. Discrepancies in the experimental results are believed to be caused by an inexact estimation of the wall boundary-layer blockage, and by 3-dimensional flow effects which are not accounted for in the 2 dimensional calculation techniques.

HEAD CLEARANCE ENVELOPE FOR EJECTION SEATS DURING NEGATIVE G sub x IMPACT ACCELERATION Channing t. Ewing In AGARD Escape Probl. and Manoeuvres in Combat Aircraft Feb. 1974 3 p. refs (For availability see N74-20758 12-051

Living volunteers from the U.S. Army participated in a research program designed to determine response of the living human head and neck to impact acceleration in 1967-1969. The restraint system used was typical of that described above and included a 3-inch lap belt, and inverted V, and shoulder straps. The seat was an experimental seat with the lavel stool stat pun parallel with the ground and the steel seat back vention! to the seat pan. The shoulder harness in all cases came straight out from the sest back to the shoulder via an adjustable spreader and then downward across the clavicles to the lap belt. The subjects so restrained were given a minus G sub x impact acceleration with fixed rate of onset and with fixed peak acceleration. The run selected for this study was that performed by an 88th percentile sitting height subject frelative to U.S. Navy pilot data), at 10G. 800G/sec with a triangular pulse, fasting about 400 ms. The subject was fitted with transducer mounts on the top of the head; mouth; and base of the nack. These mounts were sigidly attached to the anatomy and photographic targets were situsched to each mount, with two targets separated by several inches attached to the neck mount.

AN ASSESSMENT OF AERODYNAMIC FORCES ACTING

ON THE CREWMAN DURING ESCAPE

James W. Brinkley and Poter R. Payne (Payne, Inc., Annapolis)

In AGARD Escape Probl. and Manusuvres in Combat Alteraft
Feb. 1974 10 p. refs (For availability see N74-20756 12-05)

The results of analytical and experimental research accomplished to determine the magnitude of the aerodynamic forces acting on the crewman during emergency escape are summarized. The work has been directed toward the definition of the mechanisms of serodynamic field injury and the acquisition of data required for the development of protective countermeasures The results of a study of noncombat ajection experience within the U.S. Air Force during the period of 1964 to 1972 are also reviewed. This study was conducted to identify injuries attributed to serodynamic loads and to statistically describe the probability of these injuries as a function of aircraft opend at the time of ajection. Wind tunnel experiments are described which were conducted to measure the forces eating an body segments using volunteer human subjects. Both Open ejection seat and tractor rooket extraction agrees systems were studied. The data collected from these experiments includes whole body and body segment serodynamic forces. Operational variables such as arm and legposition and clothing were evaluated to determine their relative effects on the serodynamic loads soting on the subject's limbs

OPERATIONAL PRACTICALITY OF FLY AWAY EJECTION SEATS

R. Harley Walker, Jr. In AGARD Escape Probl. and Manoeuvres in Combat Aircraft Feb. 1974 15 p. refs (For availability see N74-20756 12-05)

In the interest of improving the current escape/tescue capability, a concept which provides the ejectee with increased time available for rescue by allowing him to remain sintorine out of small arms fire range and to fly with a high degree of maneuverability to a more secure, accessible area for landing and pickup is being investigated. This advanced Grew Escape and Rescue Capability, AERCAB, system provides the aircrewman with a secondary flight vehicle capabile of gaining or maintaining altitude and perhilts him to assist in his own rescue by navigating over a limited range at a specified cruise apeed out of the hostile target area toward predetermined safe sites where terminal plokup by friendly forces can be made with the least jeopardy. Thus, the AERCAB or fly away ejection system is a new dimension in airborne escape. An assessment of the potential operational practicality and effectiveness of the AERCAB system is presented. The advantages and disadvantages of the fly away escape concept in the operational environment are discussed including any penalities imposed on the tactical aircraft and missions. The probability of rescue is shown to be improved with an AERCAB system. The approach for determining the effective gost of a deployed AERCAB system is discussed.

ADVANCED CONCEPTS FOR ROTARY WING AND V/STOL AIRCRAFT ESCAPE SYSTEMS

William G. Law /n AGARD Escape Probl. and Manoeuvres I...
Combat Aircraft Feb. 1974 5 p refs (For availability see N74-20756 12-05)

The requirements for ejection seats to provide safe egress

from helicopters and V/STOL aircraft are discussed. The limitations of existing ejection seats for such applications are defined. The desirability of a display device for indicating safe ejection conditions to the crew members is expressed. The research projects which have been conducted in an effort to develop a more satisfactory ejection system are reported.

N74-20767 Naval Air Systems Command, Washington, D.C. HELICOPTER PERSONNEL SURVIVABILITY REQUIREMENTS

T. Stephen Meek In AGARD Escape Probl. and Manoeuvres in Combat Aircraft Feb. 1974 6 p ref (For svailability see N74-20756 12-05)

Current provisions for countering helicopter in-flight emergencies are discussed and their inadequacies are noted. To assess the need for improved helicopter occupant survivability, a re-law is presented of U. S. Navy. Marine Corps and Army helicopter fatal socident data. Analyses of these data have identified the survival mechanisms which could have prevented these fatalities. Practicable combinations of these survival mechanisms - (1) emergency in-flight egress, (2) improved crash impact protection. (3) improved fire protection and (4) improved flotation - could have severed more than 80 percent of the fatalities analyzed over a 17 year period.

PARACHUTE ESCAPE FROM HELICOPTERS

William P. Schane In AGARD Escape Probl. and Manoeuvres in Combat Alteraft Feb. 1974 3 p. refs (For evailability see N74-20756 12-05)

A series of parachute jumps were made from an autorotating helicopter. The exit and separation of the parachutist from the helicopter were documented by 16mm motion pictures taken at 32 frames per second with a motion picture camera and by 36mm slides taken four frames per second by a motorized Nikon camera. The photo platform was a chase helicopter flying precise formation with the jump helicopter. Data were obtained with frame by frame analysis of the motion pictures measuring the distance separating the parachutist from a reference point on the helicopter. The distance from the most enterior portion of the nose to the most posterior portion of the tall boom of the jump helicopter was used as a reference length. Approximate rates of descent of the jump helicopter during test were established using the vertical speed indicator aboard the jump helicopter. Precise rate of descent at the moment of parachutist exit was determined using a recording radar sitimater which provides precise altitude information above ground level.

N74-20769 Royal Air Force Inst. of Aviation Medicine, Farnborough (England).

HUMAN FACTORS ASPECTS OF IN-FLIGHT ESCAPE FROM HELICOPTERS

D. C. Reader In AGARD Escape Probl. and Manoeuvres in Combat Aircraft Feb. 1974 4 p refs (For availability see N74-20756 12-05)

A review of the accident statistics from some helicopters users of the NATO forces has shown that helicopter operations impose a greater risk to their crews compared with fixed-wing aircraft. Cost analyses have shown that the crew nost more to replace than their aircraft. Thus, it is considered that a strong case exists for in-flight escape from helicopters. Some human factors to be considered when designing such a system are described. Human tolerance to acceleration, egress path requirements, center of gravity data, restraint and parachete requirements, blast, noise, fragmentation and toxic hexards, and vision and egress time requirements are discussed.

ESCAPE MRASURES FOR COMBAT HELICOPTER CREWS

H. D. Melzig and U. Schmidt In AGARD Escape Probl. and Manoeuvres in Combat Aircraft Feb. 1974 11 p refs (For availability see N74-20786 12-05)

Flight-control malfunction, loss of control, loss of main or tail rotor, mid-air collision, fire explosion and transmission freeze-up occur relatively often and cause emergency conditions which can not be followed by an auto-rotation landing. Together with a very high percentage of pilot error as the responsible reason for the emergency and the operational requirements for combat helicopters with low sititude and speed, in a relatively high number of accident fatalities could have only been avoided by means of an escape system. Although the technology of cal ...ble escape systems is highly developed, its application to a hallcopter causes great difficulties because of the rotating blades A comparative analysis is made for the different modes of downward, sideward, foward and upward ejection or extraction in correlation to the expected percentage of rescue from emergencies and a number of other factors, like development cost and time, reliability, human tolerance, adaptability for retrofit and offices.

ARMY AUTOROTATIONAL ACCIDENTS

Kent A. Klimhell, Donald F. Herden, and Mark A. Hofmann. In AGARD E. in Irobl. and Manneuvres in Combat aircraft Feb. 1974. 10 p. (For availability see N74-20758-12-05).

A study reviewing autorotation accidents was initiated to ascertain the relative con "sutions that certain factors had in such accidents. The active Army, for fiscal years 1970 through 1972, was reviewed and a total of 790 accidents, or 42.3% of all accidents, were of the autorctational type. They accounted for over 89 million dollars in alteraft di, negs. 92 strotew fatalities and 852 alrorew injuries. Of these , so accounts, it was determined that personnel error alone accounted for 32.7% of the accidents, while materiel failure alone accounted for 31.4%. Of the remaining accidents (35.9%), 10.9% were attributed to a combination of personnel error and material fallure, while the remaining 15% were attributed to other causative factors. Though the total number and rate of rotary wing additions was founto be declining over the time for frame considered, the number of autorotation accidents attributed solely to personnel error was found to be on the increase, with fiscal year 1972 approximately 10% higher than 1970. The study also reviews autorom accidents in light of total accidents rates, geographical areas, aircraft, cost, fatalities, and injuries. It also provides impact data with regard to the reduction of certain parameters. Author

N74-20772 Naval Air Development Center, Warminster, Pa IN-FLIGHT ESCAPE SYSTEM FOR HEAVY HELICOPTERS

William Ogden and Gary Davis (Naval A's Systems Command) in AGARD Escape Probl. and Manoeuvres in Cor.:bat Altoraft Feb. 1974 9 p. refs (For availability see N74-20755 12-05)

The design and development of a helicopter escape and personnel survival system (HEPS) are discussed. The system contains four primary functions: (1) in flight escape, (2) crash impact energy attenuation, (3) fuel fire suppression, and (4) flotation. The configuration of the system is illustrated. Results of flight tests are reported.

IGNITION PROOFING OF FUEL TANKS [INERTAGE DES RESERVOIRS DE CARBURANT)
Georges Frechou // AGARD Alicraft Fire Safety Oct. 1976

7 p in FRENCH (For availability see N76-14059 05-03)

The following topics were discussed (1) causes of tires and flammability of fuels. (2) precautions taken to reduce the risks and the resulting problems for the aircraft designers in view of the ever more stringent competitive requirements within the aviation industry. (3) the advantage of ignition proofing fuel tanks. It is shown that an effective way to ignition proof fuel tanks is to reduce the percentage of oxygen in the gaseous mixture above the fuel, since this mixture will not be explosive if the oxygen percentage is below 9 or 10%. This however requires that the fuel tanks be pressurized to prevent outside air from entering and, furthermore, that the gases dissolved in the fuel should contain less than 10% oxygen it was consided that the resulting design and operational problems to not outweight the expected

IGNITION PROOFING OF FUEL TANKS WITH OXYGENDEFICIENT AIR OBTAINED BY DIFFUSION THROUGH A
SEMI-PERMEABLE MEMBRANE (INERTAGE DES RESERVOIRS DE CARBURANT AVEC DE L'AIR APPAUVRI
EN OXYGENE PAR PERMEATION)
Jean Tugsye // AGARD Aircraft Fire Cafety Oct. 1975 5 p

In FRENCH (For availability san N76-14059 05-03)

The possibility of using oxygen-deficient air in the Ignition proofing of fuel tanks was successfully texted in the laboratory. The oxygen-deficient air is obtained by diffusing air under pressure through a special synthetic semi-permeable membrane 0.2 micron thick, supported by a porous plate of the same material 0.2 mm thick. Depending on the temperature, oxygen will diffuse two or three times more rapidly through such a system than nitrogen. High pressure air contained within such a system will therefore become oxygen-deficient. A practical airworthy system utilizing this concept inside fuel talks must include the following systems. heat exchangers, auxiliary air compressor, and fuel deaxygenating device. The proposed system would be primarily advantageous on sircialt undergoing a large number of landings and takeoffs between refuellings, since it would then be lighter and less bulky than a system using liquid nitrogen.

FLAME PROPAGATION IN AIRCRAFT VENT SYSTEMS DURING REFUELLING

Oct 1976 9 p. refs (For availability see N78-14059 05-03)

An investigation was made to determine if ignition at the fuel system vant box of a large commercial aircraft during refuelling could result in fiame propagation through the vent system and cause an explosion inside one of the fusi tanks. The program was initiated as the result of an explosion during a commercial refuelling and was confined to investigating the type of series of aircraft involved utilizing a simulation of part of the vent system leading to the tank where the explosion originated. The ability of the flame to propagate was demonstrated using wide-cut fuel and a 50/50 mixture of wide-cut fuel and kerosens. No propagation occurred with kerosene nor with wide-cut fuel that had lost 5% of its light ends. Flame propagation and explosion intensity were found to depend on mixture temperature, fuel/nir ratio, mixture flow velocity, and oxygen content of the pir

DYNAMIC MODELING OF AIRCRAFT FUEL TANK ENVI-HONMENTS AND VULNERABILITY

Levelle Mahood In AGARD Aircraft Fire Safety Oct. 1975 9 p refs (For availability see N76-14059 05-03)

The anyionments, hazards, and vulnerability of regions adjacent to and within aircraft fuel tanks are discussed along with the importance and difficulties of developing fuel tank environment models to assess aircraft combet vulnerability and operating safety. Various approaches to modeling the flammability. of the ullage of an aircraft fuel tank are described. Examples are given to illustrate various ways that dynamic effects radically after equilibrium vapor conditions in the ullage. The method of applying the fuel tank ullage environment model to computerized aircraft vulnarability programs is described.

CABIN FINISHING MATERIALS IN CIVIL PASSENGER AIRCRAFT (LES MATERIAUX D'INTERIEUR CABINE DANS LES AVIONS DE TRANSPORT CIVILS Andra Blavv In AGARD Aircraft Fire Safety Oct 1975 3 p

In FRENCH (For availability see N76-14059 06-03)

A review of the various types of cabin finishing materials used inside civil passenger aircraft and their properties was presented, with special focus on their flammability and generation of toxic fumes when set fire. This following facts were summarized (1) materials from which fires may be easily extinguished generally emit more smoke. (2) fire-proof materials often emit toxic fumes. (3) combustion of these materials, due to their self-extinguishing properties, result in oxygen depletion and carbon monoxide formation, the primary cause of intoxication. The primary emphasis should be placed on rapid extinguishing of any incipient fire

N76-14069* National Agronautics and Space Administration Ames Research Center, Moffett Field, Calif. FIRE DYNAMICS OF MODERN AIRCRAFT FROM A MATERIALS FOINT OF VIEW

John A. Perker, Demetrius A. Kourtides, Richard H. Fish, and William J. Gilwee, Jr. In AGARD Alteraft Fire Safety Oct. 1975 | 11 p refs (For availability see N76-14059 05-03)

A general approach for selecting polymers to increase fire safety in aircraft is described. It is shown that polymer flammability and thermal protection capability are related to the molecular structure of the polymer and its thermochemical properties. These criteria are used to develop advanced fire-resistant materials which can achieve increased survivability in both post-crash and in-flight fires. The degree of fire hardening of materials depends greatly on the available heat load and fire threat present. It is shown that improvements in fire safety can be achieved by the use of polymers possessing certain basic thermochemical parameters such as high char yield.

MEASUREMENT AND ANALYSIS OF SMOKE AND TOXIC GARES RESULTING FROM THE COMBUSTION OF AIRCRAFT CABIN FINISHING MATERIALS [MESURE DES FUMEES ET ANALYSE DES GAZ TOXIQUES PROVOQUES PAR LA COMBUSTION DES MATERIAUX D'AMENAGE. MENT DE CABINE D'AVION)

J. Auvinet In AGARD Aircraft Fire Safety Oct. 1975 12 p In FRENCH (For availability see N76-14059 05-03)

The results of studies and research on the combustion of aircraft cabin finishing materials and the resulting smoke generation and production of toxic gases were reported. Results of tests measuring the concentration of the various gases resulting from the combustion of these materials were first presented, based on burning small samples under controlled conditions. Next, a near full-size mockup of a simulated aircraft cabin section, divided into passanger and freight sections by a horizontal floor. was constructed and instrumented for more realistic combustion tests. This mookup was equipped with ventilation, safety, fire extinguishing, heat protection, pressurization, lighting, and chemical analysis systems. Preliminary tests were undertaken with this mockup and were reported.

SOME ASPECTS OF SMOKE AND FUME EVOLUTION FROM OVERHEATED NON-METALLIC MATERIALS

A. J. Christopher In AGARD Aircraft Fire Safety Oct. 1975 12 p refs (For availability see N76-14059 05-03)

įί

A dynamic system for assessing the smoke and fume emission characteristics of nonmetallic materials is described. A sample of the material under examination is heated from ambient to 500 C in a stream of air. The behavior of the material under in-flight electrical overheating conditions is simulated. Sample temperature, smoke density, and electrode response in a water bubbler are monitored. Results obtained for various materials are presented and discussed.

FLAME SPREADING ACROSS MATERIALS: A REVIEW OF FUNDAMENTAL PROCESSES

William A. Sirignano In AGARD Aircraft Fire Safety Oct.

1975 12 p refs (For availability see N76-14059 05-03)

A critical review of the existing researches on flame spread above solid combinatible materials is given; both theory and experiment are considered. Special attention is given to the determination of the rate-controlling mechanism for energy transfer shead of the flame and therefore to the determination of the flame spreading rate. The mechanism could be either gas-phase conduction, radiation, gas-phase convection, or some combination of these. Important factors discussed include: natural convective flows, orientation of the direction of flarne spread with respect to gravity, thickness of the burning material, and the values of the conductivity, diffusivities, heats of reaction and pyrolysis, chemical kinetic constants, and ambient oxygen concentration. It is indicated how changes in these factors can produce changes in the rate-controlling mechanism.

N75-14075 Deutsche Forschungs- und Versuchsanstalt füer Luft- und Raumfahrt, Porz (West Germany). ON THE APPLICABILITY OF RETICULATED FOAMS FOR THE SUPPRESSION OF FUEL TANK EXPLOSIONS

R. Fials, K. Dussa, and G. Winterfeld In AGARD Aircraft Fire Safety Oct. 1975 12 p rafs (For availability see N76-14059 05-03)

The flame suppression properties of polygrethane foams with varying cell size were studied by means of a flame tube and an explosion vessel. Results on the thickness of the foam layer necessary for flame quenching are given, depending on pore size, fuel-air ratio, and on pressure. The behavior of reticulated foam during explosion in a closed vessel is discussed, as well as its mechanical behavior. Conclusions with respect to the application of foam structures in tanks are presented Author

THE USE OF ROCKETS AGAINST CRASH FIRES IN AIRPORT AREAS

M. Andrenucol In AGARD Aircraft Fire Safety
12 p. refs (For availability see N78-14059-05-03)

The use of rockets is proposed as a means of fighting crash fires, due to their quickness, easy operation, and ability to reach sites not readily accessible by other means. Possible vehicle configurations are discussed along with system operating modes. Details are given of a simulation study, intended for providing the major specifications for the system components performance with respect to efficacy, reliability, and safety requirements. Cost factors are considered.

N76-14080 Deutsche Forschungs- und Versuchsanstalt füer Luft- und Raumfahrt, Porz (West Germany) FIRE FIGHTING AGENTS FOR LARGE AIRCRAFT FUEL

FIRES

R. Fials and K. Dussa In AGARD Aircraft Fire Safety 1975 10 p refs (For availability see N76-14059 05-03)

For a critical evaluation of the properties of the different types of agents experiments were carried out using standardized small and large fuel fires (4 sq m and 200 sq m). The time until extinguishment occured and the amount of agent needed, were measured. Additionally, the time which, after a deliberate reignition, elapsed until the whole fuel surface was on fire again, was measured. Results are discussed.

N76-14081 Joint Fire Research Organization, Boreham Wood (England). Extinction Section

THE EXTINCTION OF AIRCRAFT CRASH FIRES
P Nash In AGARD Aircraft Fire Safety Oct. 1975 13 p. refs (For availability see N76-14059 05-03)

The problems are discussed of the aircraft crash fire, including the difficulty of arrival of the fire-fighting services in time to save life. The different fire fighting agents available are appraised. Fire fighting feams are shown to be the only satisfactory primary fire fighting agents for major crash fire use. The research and development of foam liquids and the means used to assess their performance are discussed in terms of the physical properties of the foam liquid. The development of foam making equipment and appliances in order to put the foam liquid to best use to meet the operational requirement is examined.

N76-14082 Federal Aviation Admiristration, Atlantic City, N.J. CHARACTERISTICS OF HALON 1301 DISPENSING SYSTEMS FOR AIRCRAFT CABIN FIRE PROTECTION Constantine P. Sarkos In AGARD Aircraft Fire Safety Oct.

1975 16 p refs (For availability see N76-14069 05-03) A cabin fire protection system using Halon 1301, an extinguishing agent proviously tested and shown to be effective in suppressing and controlling fires in a simulated transport cabin. section and a cargo compartment is investigated. Tests were conducted in an obsolete but completely furnished DC-7 passenger cabin equipped with two candidate Halon 1301 dispensing systems: modular nozzle and perforated tube. Under no-fire conditions, continuous measurements were made of the Halon 1301 concentration at approximately 20 locations; measurements were also made of temperature, noise, pressure, and visibility. The modular nozzle system was judged to be best by virtue of its producing more rapid and effective agent distribution resulting in greater potential fire protection capability. Halon 1301 was found to rapidly permeate all cabin airspaces, including those shielded from the discharge streamlines Author

N76-14063 Karlsyuhe Univ (West Germany) A LABORATORY TEST METHOD OF EVALUATING THE EXTINGUISHING EFFICIENCY OF DRY POWDERS Paul G. Seeger In AGARD Aircraft Fire Safety Oct. 1975 9 p refs (For availability use N76-14059 05-03)

The laboratory test method of avaluating the estinguishing efficiency of dry powders is based on the burning velocity of a laminar premixed methane-air flame. The dry powder being tested is fed into the premixed fuel gas-air flow by a vibrating chute. The powder particles reach the test flame and reduce the burning valority more or less depending on their extinguishing efficiency The burning velocity is determined by the nozzle method and by aphlieren photography. The evaluation of the measurements shows that the square of the burning velocity is a linear function of the mass flow of the dry powder fed into the fuel gas-air flow. The theoretical minimum value of the mass flow of the dry powder necessary to extinguish the test flame may be determined by the slope of the straight line.

N76-14084 Pinkel (I. Irving), Fairview Park, Ohio. DYNAMIC EFFECTS IN THE SETTING OF AIRPLANE CRASH

Irving Pinkel In AGARD Aircraft Fire Safety Oct. 1975 p (For availability see N76-14059 05-03)

The principal features of simplene crash dynamics are described. Fectors considered include: fuel spillage: movement of spilled fuel to main ignition sources; propagation modes of fire to the main spillage and the fuel tank opening. Some of the main factors in the ignition and apread of fire are illustrated with slow motion pictures of full-scale airplane crashes. Author

FIRE, FUEL AND SURVIVAL: A STUDY OF TRANSPORT
AIRCRAFT ACCIDENTS, 1865 - 1974
A. F. Taylor /n AGARD Aircraft Fire Salety Oct. 1975 14 p

refs (For availability see N76-14059 05-03)

Accident summaries and reports are examined together with existing papers on the various aspects of fire safety, the aim being to piece together a complete picture of the part fire has had in determining overall fatality rates in transport aircraft accidents. Note is taken of the sensitivity of the fire death ratio to the number of high impact accidents with no chance of survival and of how this sensitivity may have clouded some past comparisons between fuels of different volatility. It is indicated that in post impact fires the higher volatility fuels, gasoline and wide-cut gasoline, have been responsible for proportionately more fire deaths than has low volatility kerosine, thus confirming predictions based on theory and experiment.

N76-14086 Swissair, Zurich (Switzerland). PASSENGER AIRCRAFT CABIN FIRES

Willi Schurter In AGARD Aircraft Fire Safety Oct. 1975 5 p. (For availability see N76-1405B 05-03)

After a brief review of the established findings on the crash of a Swisseir Coronado CV-990A in Wirrenlingen, Switzerland, on February 21, 1970, an enalysis of the cabin fire preceding the crash is given, including origin of fire, its propagation and effects on the aircraft systems. A method of establishment of elevated local temperatures in cargo compartment and cabin by means of uncommon fractures as found in the wrackage is described. The role played by the major aircraft systems is discussed. Furthermore, since the smoke spreading in cabin and cockpit is considered the factor rendering the aircraft uncontrollable under the prevailing conditions, the results of tests carried out simulating the smoke conditions are given.

N76-14087 Secretariat General e l'Aviation Civile, Paris (France). CRACH OF THE PP-VJZ AIRCHAFT [L'ACCIDENT DU

P. Guillevic In AGARD Aircraft Fire Safety Oct. 1975 6 p In FRENCH (For availability see N76-14059 05-03)

The results of investigations that followed the crashes of two aircraft (a Caravelle in 1968 and a Boeing 707 in 1973) following fires that started in regr washrooms were reported. In both cases, it was concluded that fatalities were primarily caused by intoxication resulting from the inhalation of carbon monoxide and highly acidic toxic vapors such as chlorhydric acid and cyanhydric acid originating in the combustion of cabin finishing materials.

ADVANCED TECHNIQUES IN CRASH IMPACT PROTEC-TION AND EMERGENCY EGRESS FROM AIR TRANSPORT

R G. Snyder (Michigan Univ., Ann Arbor). Jun. 1976 320 p.

(AGARD-AG-221) AGARDograph-221; ISBN-92-838-1218-9)

Copyright. Avail: NTIS

Analysis of all NATO member air transport accidents, 1984-1975, revealed that injuries and fatalities, when such information could be determined, were primarily due to the post-grash effects of fire, smoke and toxic fumes, and secondarily to crash impact. Future air transport design trends were reviewed. and approximately 150 advanced crash-impact and amergencyegress concepts, devices, and state-of-the-art techniques were evaluated. These included occupant restraints, smoke hoods, aisle and agress emergency lighting, passenger warning systems, escape slides and devices, heat shields, high-energy amergency agress systems, and emergency inflight agress systems. It was concluded that rear-feeling passenger seats, the NASA Ames (21 + 6 sub x sub 45+6 sub z) airline seat, and the production sheldahl smoke hood can provide significantly improved occupant protection, while high-energy emergency egress systems appear promising for future attoraft. More research is needed to improve passanger warning and public address systems. Concepts of emergency inflight egress are not yet feasible, although technically within the state-of-the-ort.

THE PHYSIOLOGY OF COLD WEATHER SURVIVAL

A. Borg, ed. (Roy. Norweg, Air Force) and J. H. Veghta. ed. (AMRL, Wright-Patterson AFB, Ohio) Jun. 1974 99 p refs (AGARD-R-620) Avail: NTIS HC \$8.00

Physiological factors and emergency life sustaining measures are outlined for aircrew survival in a cold winter region. For Individual titles, see N74-33535 through N74-33545.

N74-33536 Oslo Univ. (Norway). Thenmogenetic mechanisms involved in man's Fitness to resist cold exposure

K. Lange Anderson In AGARD The Physiol. of Cold Weather Survival Jun. 1974 p 1-6 rate (For availability see N74-33534 23-04)

The main factor by which man's fitness to resist cold exposure can be varied, appears to be thermogenesis. The biological varietion of BMR, shivering, a possible non-shivering thermogenesis, and the maximal aerobic power is reviewed. BMR of an individual can vary with diet, general health, habitual physical activity, as well as various environmental conditions, conceivably including cold exposure. A definite inter- and intra-individual varietion in shivering threshold exists. Man's capability to reise his metabolism in muscular exercise is an important part of his fitness to resist cold exposure. This capability can be essessed by measurement of maximal oxygen uptake. Maximal oxygen uptake is influenced by age, sex, health, diet and habitual physical activity.

PERIPHERAL CIRCULATORY ADJUSTMENT TO COLD
Jorin Krog In AGARD The Physiol, of Cold Weather Survival
Jun. 1974 p 7-15 refs (For svallability see N74-33534 23-04)

Measurements of blood circulation in the hands and faces of Arctic people are compared with those on Norwegian lumberjacks and city dwellers. Obtained date for time of onset of vasodilation, amount of vasodilation, and pressure response following cold stimulation indicate that the greater tolerance to cold in Arctic people is due to an adjustment of the vasomotor control in the pheripheral tissue, in such a way that the initial vasoconstriction response is less severe and lasts shorter. G.G.

N74-33537 Royal Norwegian Air Force, Oslo. INTRODUCTION TO WINTER SURVIVAL

Rolf A. Grimerud and Claus Moelbach-Thellessen. In AGARD The Physiol. of Cold Weather Survival. Jun. 1974 p 17-28 (For availability see N74-33534 23-04)

In winter man cannot stay in the open and expect to live unless he is on the move. He needs a shelter of some kind even if it is only a hole in the snow. It should be kept in mind that a wind of 10 knots equals a fall in temperature of approximately 30 deg delsius on the skin compared with that experienced in quiet weather. The type of shelter to be built will depend on: (1) tools and material available; (2) snow conditions; and (3) the length of time of expected residence in that particular location. Allorew must remember to adjust their clothing while working. Sweating should be avoided. Emergency signalling equipment should be readily available at all times and the camp site should be made as conspicuous as possible from the sir.

LOCAL EFFECTS OF ACCLIMATIZATION TO COLD IN

Bjorn Helistrom In AGARD The Physiol. of Cold Weather Survival Jun. 1974 p 41-51 refs (For availability see N74-33534 23-04)

The mechanisms underlying local manifestations of cold acclimatization are not fully known, but point to a central nervous habituation to cold exposure. This primitive type of learning is characterized by a diminishing response upon repeated stimulation. It is common experience that the discomfort caused by cold is reduced by repeated or prolonged cold exposures. There is also emple evidence that shivering is reduced with repeated cold exposures. These reductions of physiological reactions to cold upon repeated exposures to low ambient temperatures point towards a central nervous habituation as the main mechanism of cold acclimatization in man.

N74-33840 Oslo Univ. (Norway). Inst. of Work Physiology. A PHYSIOLOGICAL COMPARISON OF THE PROTECTIVE VALUE OF NYLON AND WOOL IN A COLD ENVIRONMENT.

Kasre Rodahl, Fredric A. Giere, Peer H. Staff, and Bertil Wedin In AGARD The Physiol. of Cold Weather Survival Jun. 1974 p 53-57 refs (For availability sep N74-33534 23-04)

Similar inner garments of nylon pile and of wool pile were compared in paired experiments at rest for one hour and during two hours fairly strenuous physical activity (treadmill welking at 100 m/min, 5% incline) followed by two hours rest in a climatic chember at -20 C. Each subject served as his own control, participating in experiments using both types of experimental garments. Under these conditions no significant difference could be detected between the two types of garments in terms of thermal insulation, nor in the ability of the two types of fabric to allow free escape of moisture produced by sweating during physical activity.

The relation of the controller to automation in air traffic

control is discussed in terms of human factors engineering. Concepts discussed include: task changes and automatism, workload, quality of navigation sid, training, potentially incompatible sims, effects of automation on task design, and automation and communication.

N75-32052 Messerschmitt-Bosikow-Blohm G.m.b.H., Munich

THE FUTURE POSITION OF THE CONTROLLER

Klaus Brauser and Ruediger Seifert In AGARD A Survey of Modern Air Traffic Control, Vol 1 Jul 1975 p 63-74 refs (For availability see N75-32047 23-04)

The problem of automation of ATC systems was shown to be a very complex task, concerning three different control loops with different control loops were defined as executive (rader) control with the tasks of teolical intervention; planning control, with the tasks of procedural planning; and flow control. It was found that the human responsibility for air traffic safety cannot be delegated, but that there are many human activities which can be defined as black box actions performed more efficiently by computers. The resulting system is characterized as a highly effective human control system with an optimun amount of automatic devices to perform routine tasks as well as an effective decision aid with good on-line characteristics.

THE PSYCHOLOGIST'S VIEW

V. David Hopkin In AGARD A Survey of Modern Air Traffic Control, Vol. 1 Jul. 1975 p 77-102 refs (For availability see N75-32047 23-04)

The role of human factors in air traffic control depends on the stage at which it is first applied. The psychologist's contribution is most effective early in the system evolution, when he can forestell problems as well as cure them. In studying air traffic control systems, ideally the psychologist uses system and job analysis, which he can both conduct and interpret. Aspects of the man-machine interface, such as displays, controls and communications, sie optimized in relation to the efficiency and well-being of the men. His knowledge of differences between men is applied to recruitment, selection, training and screening. The effects of againg and of experience are predicted from known progressive changes within each individual. Knowledge of the capabilities and tolerances of the man is used to solve problems of work-rest cycles, stress and workload. To solve these problems, the psychologist uses orthodox methods and specially devised techniques for assessing and measuring the man at work.

DATA PROCESSING FOR ATC

Horst A. Neumann /n AGARD A Survey of Modern Air Traffic Control, Vol. 1 Jul. 1975 p 159-172 refs (For availability see N75-32047 23-04)

There are two main objectives of data processing for air traffic control: first, support of tectical control by the provision of a sophisticated display of the air traffic situation and by the application of procedures of resi-time conflict detection and solution; second, avoidance of air traffic congestion as well as reduction and balancing of the load of both the planning and the executive controller by automatic filtering of conflicts and by hierarchical structuring of planning and control functions. Features and criteria of functions termed flow planning, flow control and flight progress planning and control to achieve the second objective with the application of electronic data processing are considered.

AUTOMATION IN AIR TRAFFIC CONTROL SYSTEMS Adi J. Khambata In AGARD A Survey of Modern Air Traffic

Control, Vol. 1 Jul. 1975 p 175-198 refs (For availability see N75-32047 23-04)

Controlling the ever-increasing number of sircraft movements In an orderly and safe manner in the nation's airspace is becoming a problem. The historical evolution is traced of Air Traffic Control (ATC) since before World War II. It also discusses the current ATC problems. The National Airspace System (NAS) design concept is presented, and the progress made in implementing it in the enroute area is described. The progress of automation in the terminal areas Include systems such as the unique Common IFR Room at New York, one of the world's most congested metropolitan terminal areas, and the recently installed ARTS III System at O'Here Field in Chicago, which is considered the world's businest air terminal. Several other areas of automation, such as collision avoidance, which impact the ATC system, are also discussed.

N75-32089 Office National d'Etudes et de Recherches Aerospatiales, Paris (France).

CONFLICT AND COLLISION AVOIDANCE SYSTEMS
Roland Moreau In AGARD A Survey of Modern Air Traffic Control. Vol. 1 Jul 1975 p 203-238 refs (For evailability see N75-32047 23-04)

Greater flight safety dispite the growth in traffic by improved air traffic control was investigated. The means of ensuring greater safety for successive phases of a flight from takeoff to landing. errborne collision avoidance systems (CAS), and ATC/CAS compatibility are discussed.

N75-32060 Mitra Corp., McLean, Va. CONFLICT ALERT AND INTERMITTENT POSITIVE CON-

Lawrence G. Culhane and Barry M. Horowitz In AGARD Survey of Modern Air Traffic Control, Vol. 1 Jul. 1975 p 241-256 refs (For availability see N75-32047 23-04)

Analytical, simulation and experimental results are presented which were obtained in the process of designing and progressing toward the implementation of ground-based collision avoidance systems for air traffic control. Selective subsystem performance criteria established as part of the design process are also presented. Different, but compatible system concepts are discussed. For situations involving IFR aircraft, a conflict alert capability will provide the controller with a displayed alert of impending situations of separation being less than minimums. An Intermittent Positive Control (IPC) function, utilizing data link and improved surveillance. provides an automated collision avoidance capability for VFR/VFB and VFR/IFR alteraft pairs, and provides an independent backup to the ATC system for IFR aircraft pairs. In addition, IPC includes pilot warning indications (PWI) for informing pilots of the location of proximate aircraft

N75-32061 Federal Aviation Administration, Washington, D.C. AIR TRAFFIC FLOW CONTROL

Michael E. Perie, Juan F. Bellantoni, and Ian G Wolf in AGARD A Survey of Modern Air Traffic Control, Vol. 1 Jul. 1975 p 261-278 refs (For availability see N75-32047 23-04)

The major operational problems in controlling the general flow of the nation's air traffic from a central facility are described. and some of the approaches that may be taken to help automate their solutions are outlined. The discussions are based on operational experience at the FAA's Air Traffic Control Systems Command Center and on the present prototype computer programs, developed by the Transportation Systems Center, that provide data processing support to the controllers at that facility. The operational problems, giving the history, present procedural techniques and constraints, data sources, and control strategies available are described. Some of the pitfalls in solving the operational problem. Various approaches to automating flow control such as quantifying the objectives and developing algorithms to assist the controllers are discussed

APPLICATION OF MODERN CONTROL THEORY TO SCHEDUUNG AND PATH-STRETCHING MANEUVERS OF AIRCRAFT IN THE NEAR TERMINAL AREA

Michael Athans In AGARD A Survey of Modern Air Traffic Control, Vol. 1 Jul. 1978 p 297-322 refs (For availability see N75-32047 23-04)

A design concept is presented for the dynamic control o aircraft in the near terminal area. An arbitrary set of nominal air routes, with possible multiple merging points, all leading to a single runway is considered. The system allows for the automated determination of acceleration/deceleration of aircraft along the numinal air routes, as well as for the automated determination of path-stretching delay maneuvers. In addition to normal operating conditions the system accompdates variable commanded separations over the outer marker (to allow for takeoffs between successive landings); and emergency conditions (in the sense that an aircraft is given partial or complete priority for landing). The system design is based upon the combination of three distinct optimal control problems: (1) a standard linear-quadratic problem. (2) a parameter optimization problem, and (3) a minimum-time rendezvous problem. Simulation results involving twelve sircraft under both normal and emergency conditions are presented.

AIRCRAFT TRAJECTORY PREDICTION DATA FOR ATC

Andre Benoît and Elleen Evers (SCICON, Ltd., London) /// AGARD A Survey of Modern Air Treffic Control, Vol. 1 Jul. p 327-367 refs (For evailability see N75-32047 23-04)

A method is presented for assembling the aircraft trajectory data in a compact form which indicates the quality of the aircraft characteristic data produced. The main aspects are outlined of an EROCOA aircraft performance handbook which is being prepared. The method covers all phases of the flight with the exception of the takeoff and initial acceleration, final deceleration and landing. Climb, acceleration and deceleration at cruising level. cruise and descent are considered equally and data are assembled in order to compute the trajectory components during any of these phases. The data produced cover a floet of over one hundred aircraft versions including sixty different sircraft types, namely most of the current commercial aircraft operating in Western Europe and manufactured in Europe of North America and a sample of aircraft specifically designed for military purposes

MEDIUM DISTANCE AIDS (VHF OMNIDIRECTIONAL RADIO BEACONS)

Guenter Hoelgen In AGARD A Survey of Modern Air Traffic Control, Vol. 2 Jul. 1975 p 425-433 refs (For availability see N75-32066 23-04)

VHF omnidirectional radio range (VOR) is a radio aid for aircraft guidance; it is an omnidirectional radio beacor, providing the angle between aircraft and North, seen from the ground station. The VOR ground station radiates an azimuth-dependent signal which is analyzed as the bearing information by the shroat receiver. The pilot guides the shroraft along the course selected with the sid of constant szimuth indication. The range is of the order of 100 to 150 nm.

DISTANCE MEASURING METHODS

Manfred Boehm /ri AGARD A Survey of Modern Air Traffic Control, Vol. 2 Jul. 1975 p 437-446 (For availability see N75-32066 23-04)

The distance-measuring methods employing electromagnetic waves make use of the velocity of light; the path covered by a light or radio signal can be determined, if the transit time is known, from a formula. Round-trip and one-way distance measuring systems are described; the round-trip systems operate with responding transmitters (or with passive reflectors as in the case of radar or radio eltimeters), and the responding transmitter will retransmit the received signal with an exactly defined delay. In the name of one-way distance-measuring systems, identical and extremely accurate time standards are used in both the transmitter and the receiver locations. Airborne and ground station equipment is discussed.

GENERAL ASPECTS OF DATA FLOW

Horet A. Neumann In AGARD A Survey of Modern Air Traffic Control, Vol. 2 Jul. 1975 p 639-645 rafs (For availability see N75-32066 23-04)

Regarding complex systems such as air traffic control, date acquisition and data processing are performed through cooperation of man with machine, indispensable dialog usually is accomplished by nutput of machine's results via teletypes, lineprinters, piotters, or luminous data displays and by input of man's acquired data, results, and decisions via functional keys, keyboards, and touch displays. A block diagram of data flow in air traffic control is presented. Manual data input is combined with data acquisition; data output is differentiated with respect to the receiver (pilot and controller). The diagram, as seen from a general point of view, represents implicitly all possible concepts of air traffic control executed on-ground, including even the concept of manual control, which leaves time-consuming tasks of data acquisition and preprocessing as well as all grupial tasks of intrinsic data processing to controllers.

N75-32078 Messerschmitt-Boeikow-Blohm G.m.b.H., Ottobrunn (West Germany

SOME TRENDS IN HARDWARE CONCEPTS FOR ATC COMPUTER

Wolfgang Nittner In AGARD A Survey of Modern Air Traffic Control, Vol. 2 Jul. 1975 p 649-656 refs (For availability see N75-32066 23-04)

Four main requirements are discussed for hardwarestructures resulting from applications such as radar data tracking, conflict detection and resolution, long-term flight plan coordination and flow control, flight progress adjustment, recording, and statistics application programs: reliability and safety, storage capacity and processing power, time behavior, and hardware-software-integration and software related features. Technologies and important features of computer structures are outlined.

FOUR-D NAVIGATION IN TERMINAL ZONES: AN AUTOMATIC CONTROL PROBLEM

Marc J. Pelegrin In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 25 p refs in ENGLISH and FRENCH (For availability see N76-23191 14-04)

It is shown that, if a velocity profile is imposed upon the plane and controlled along a selected approach path, it is possible to limit the deviation from the computed arrival time of the plane at the ILS entry gate. Two simulation programs, a fast time one and one in real time, determine and control the optimum 4-D trajectory. The first results show that the accuracy of the simulation need not be very great; thus, the extra computing ground capacity is fairly limited. It can also be shown that an accurate descent trajectory is no problem for an aircraft equipped with an automatic throttle command. Moreover, a head-up display

that gives the optimum glide slope angle allows a very accurate control of the plane along its longitudinal exis. Author

N76-23194 Bosing Commercial Airplane Co., Seattle, Wash, STRATEGIC CONTROL OF TERMINAL AREA TRAFFIC Raiph L. Erwin, Jr. In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 13 p. refs (For availability see N76-23191 14-04)

An advanced method of controlling air traffic in high density terminal areas is reported. In this concept the air traffic control system defines four dimensional tracks for all arrivals that will derandomize and space the traffic for landing on the runway. The aircraft use four dimensional navigation and guidance aquipment to fly the assigned paths. The adventages that result from a strategic control system using airborne four dimensional navigation and guidance equipment are presented; the resulting benefits of increased capacity and reduced fuel consumption are discussed. The logic used by the air traffic control authority to strategically control arrivals is described. This logic determines the sequence for handling the aircraft, establishes the time schedule for use of the runway by each flight, and calculates the four dimensional path to be assigned to each sircraft. recognizing the seroperformance capabilities of the individual flight. The performance of the algorithm is demonstrated by the results of a fast time simulation of etrategic control as applied to arriving traffic for Los Angeles International (LAX) Airport.

ATC CONCÉPTS WITH EXTENSIVE UTILIZATION OF AUTOMATIC DATA PROCESSING

Horst Newmann In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 S.p. (For availability see N76-23191 14-04)

Alternative concepts of electronic data processing supported ATC are outlined and technical and procedural problems are specified in each case. Emphasis is on conceivable planning functions and logical relations with air traffic control functional leading to semi-automatic air traffic control. There are two main effects of such an ATC concept utilizing sutomatic data processing extensively: (1) expedition of the air traffic flow and reduction of the load of both the planning and the radar controller, because automatic filtering of confilets will be achieved; and (2) optimum balancing of the load, because automatic allocation of flights to controllers will permit more dontinuous control and guidance with joint control sectors.

OMEGA: A SYSTEM WHOSE TIME HAS COME

John F. Beran and John E. Bortz, Sr. (Analytic Sciences Corp., Reading, Mass.) In AGARD. Plans and Develop, for Air Traffic Systems. Feb. 1976. 10 p. rofs (For availability see N76-23191.14-04).

The United States Air Force program to equip approximately 700 airlift aircraft with Omega navigation equipment is described. The program structure emphasizes obtaining low cost automatic equipment satisfying onroute air navigation performance requirements. Required equipment obstated sits are identified and the structure of the equipment acquisition program is outlined. Several important Omega technology issues are discussed from a user's perspective. The paper concludes with a summery of the results of an Air Force flight test program designed to evaluate the important technology options now svaliable in Omega navigation equipment.

N76-23197 Plessey Rader Ltd. Havant (England). A SURVEY OF PRIMARY RADARS FOR AIR TRAFFIC SYSTEMS

K. Milne In AGARD Plans and Develop, for Air Traffic Systems Feb. 1978 10 p. refs (For availability see N76-23191 14-04)

Application areas for primary radars in air traffic systems are reviewed. Problems facing the designers of such radars are outlined. Minimization of ground clutter, precipitation clutter and angle schoes figure high on the list of desiderats, combined with the needs for adequate data rate and high equipment reliability. Approaches to the solutions of these problems are surveyed and examples given of current practice. Future trends in primary radars are discussed in the light of recent advances in sutomation and in signal processing techniques. Improvements in the immediate future are likely to be evolutionary in nature, similar at making the performance of today's radars compatible with more automated control systems.

N76-23198 Federal Aviation Agency, Washington, D.C. Systems Research and Development Service.
ATCRES IMPROVEMENT PROGRAM

Martin Natchipolsky In AGARD Plans and Develop for Air Traffic Systems Feb. 1976 10 p (For availability see N76-23191 14-04) (ARD-241)

The Air Traffic Control Radar Beacon System (ATCRBS) experiences a number of problems such as false, broken, fading, missed and garbled targets. Although many factors contribute to the degradation of ATCRBS performance, most problems can be attributed to poor interrogator/receiver antennas, the difficulty of interrogator management, inadequate reply target detection and processing criteria or airborne transponder performance. A major development effort has been directed at improved interrogator antenna designs because the present FAA ATCRBS antenna is responsible for many of the system problems. Planned development efforts for improved ATCRBS reply processing and target detection are based on utilization of the improved antenna performance and sum difference pattern capability for monopulse processing.

in part by FAA (For availability see N75-23191 14-04)

ADSEL/DABS (Address Selection/Discrete Address Bescon

ADSEL/DABS (Address Selection/Discrete Address Beacon System) is a selectively addressed secondary radar system which is an extension of present day ATCRBS/SSR. The system provides the usual surveillance data, identity, height and position and in addition a data link communication facility is available on both the ground to air and air to ground channels. The system is entirely compatible with present day ATCRBS/SSR and introduction can take place over an extended period. A modified transponder is required in the aircraft which operates on both normal ATCRBS/SSR and ADSEL/DABS. The new ground stations can provide surveillance of aircraft fitted with existing ATCRBS/SSR transponders as well as handling those with selective address transponders on board. An overall description of the system is given together with details of the message formats and modulation techniques adopted.

LEA MICROWAVE APPROACH AND LANDING SYSTEM Roberto Nicoli In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 5 p (For availability see N75-23191 14-04)

The system operates in time sharing for terminal area navigation and landing or runway taxiing side. In addition to the over 100 aircrafts that the system is capable of assisting in the landing phase, it can provide TMA navigation aid to several hundreds aircrafts inside a 30 n.m. radius area. The system utilizes a simple airborne equipment, while the ground equipment can be implemented at various degrees of sophistication, according to the airport size and traffic. Aircraft position data and identification are simultaneously available enboard and on the ground so that TMA and ATC are simplified. On the ground, ATC personnel have available data of all alteraft in TMA, landing or taxing in the runways, complete with the sircraft indentification codes. The pilot has evailable onboard-- on standard cockpit instruments-the accurate position data of the aircraft in relation to the airport for TMA and to runway for landing. The ATC operator who monitors the aircraft situation on a scope gives ground-to-sir instructions for TMA to the pilots and emergency communications for landing.

MATCALS: EXPANSION OF CAPACITY FOR EXPEDITIONARY AIRFIELDS
Richard R. Wilz (Marine Corps., Washington, D. C.) In AGARD

Plans and Develop, for Air Traffic Systems Feb. 1978 18 p (For availability see N76-23191 14-04)

The Marine Air Traffic Control and Landing System (MATCALS) is being implemented to upgrade and automate the ATC and all weather landing control capabilities of Marine Air Traffic Control Units (MATCU). The overall role of Marine Corps

aviation is reviewed, and the crucial role and operational functions of the MATCU as a supporting element are described. An overview is presented of the MATCALS implementation program, the system as a whole, and the advanced capabilities which MATCALS will provide. Specific functional capabilities for air traffic management and control are indicated, and the technical approach toward implementing these functions is described. The MATCALS lending control capabilities and functions are then described, with emphasis on the operational advantages realized with an automated ground derived system. Finally, the impact of MATCALS on overall Marine aviation effectiveness is summarized. This summary emphasizes the quantitative factors by which MATCALS will increase the maximum rate of air firepower delivery through increased traffic handling capacity at expeditionary artifulds.

ADVANCED ATC AUTOMATION: THE ROLE OF THE
HUMAN IN A FULLY AUTOMATED SYSTEM
Righerd A, Rucker /// AGARD Plens and Develop, for Air

Traffic Systems Feb. 1976 10 p refs (For availability see

N76-23191 14-04)

An overview is presented of one approach to formulating and evaluating an experimental model which automates routine an route sector traffic con rol. Basic design concepts are identified, and the automated control tasks performed by the Front Royal sector model, a digital computer simulation, are discussed. The paper then focuses on the anticipated roles and responsibilities of the journeyment air traffic controller in such an environment and how an route sector position designs may further evolve as a result. The purpose is to explore some long range implications and potentials from the perspective of the air traffic controller.

THE PROVISION AND USE OF INFORMATION ON AIR

TRAFFIC CONTROL DISPLAYS

V David Hopkin In AGARD Plans and Davelop, for Air Traffic

Systems Feb. 1976 12 p refs (For availability see N76-23191

Several kinds of mismatch can copur at the man machine interface in air traffic control systems. One, often overlooked, concerns the provision of certain essential information in a form which is unusable. The traditional reliance on the man's strengths of adeptability and flexibility in order to match man and machine in the system is thewarted if he cannot use the information presented to him. Changes from qualitative to quantitative information, incomplete automation, and the apparent retention of decision making roles which in fact have been greatly modified, all pose problems of ensuring that the displayed information has been adapted successfully.

AUTOMATION OF LOCAL FLOW CONTROL AND METERING OPERATIONS IN THE ENROUTE/TRANSISTION ENVIRONMENT

Robert S. Ratner In AGARD. Plans and Develop for Air Traffic Systems. Feb. 1976. 7 p (For availability see N76-23191 14-04).

Local flow control procedures are described that are used when a sector of the enroute/transition airspace becomes saturated, in terms of the workload or control depactly of the sector control team. The procedures are generally implemented according to prespecified plans, and take the form of restrictions on the permissible in-trail inter-aircraft separation for traffic flows upstream of the impacted sector. The describility of enhancing this process of local flow control is discussed. A concept, rermed planning control, for enhancing local flow control operations through automation, is described. The concept is based on prediction of prospective traffic levels on routes and in sectors within an air route traffic control center, using the on-line traffic data base of the NAS Enroute Stage. A system Appropriate flow control restrictions, are instituted whenever control workload in a sector exceeds a standard level.

THE OPTIMISATION OF TRAFFIC FLOW AROUND A
METWORM

V. W. Attweell. In AGARD. Plans and Develop, for Air Traffic Systems. Feb. 1976. 8 p (For availability see N78-23191 14-04)

The use of flow control is considered for air routes subject to saturation. Alterations to intended flight times at the planning stage penaltze the operator, but so do the delays from concestion which occur if such alterations are not made. Hence there is an optimum balance which can be expressed as a planning target flow rate on a given route. For a network of routes subject to constraints, similar considerations lead to an optimum planned distribution of traffic flow around the system. The assessment of this optimum can become complex and is best handled by computer optimization techniques. The use of such techniques may become inevitable when the increasing complexity of route systems and constraints makes it impracticable for the unaided human brain to approach an optimum traffic distribution. Our study is illustrated by examples of traffic conditions at the England/France boundary. Author

INTERACTIVE CONFLICT RESOLUTION IN AIR TRAFFIC
CONTROL

R. G. Ball, R. B. Lloyd, and G. Ord. /n AGARD. Plans and Develop, for Air Traffic Systems. Feb. 1976. 14 p. refs. (For

availability see N76-23191 14-04)

Aircraft of the major operators are becoming more and more capable of flying trajectories well defined in space and time. Such trajectories offer distinct advantages to operators and could also offer advantages to controllers for planning conflict free situations in the tactical phase of control. However, in order to use them. It is necessary for controllers to be able to visualize the trajectories further into the future, and in greater detail, then they can at present. A technique is outlined for improving the controller's visualization ability by using computer assistance to provide a predictive display. The technique is capable of being extended to help the controller with conflict detection and resolution. An important feature of the extension is that it allows the controller to conduct a dialogue with the computer enabling him to try out various options, the outcome of each of these being displayed so that he can assess the consequences of any action. The paper clao discusses how the computer can assist with monitoring that aircraft remain on trajectories which are conflict free. Author

N76-23205 Federal Aviation Agency, Washington, D.C. INTERMITTENT POSITIVE CONTROL: A GROUND-BASED COLLISION AVOIDANCE SYSTEM

Michael E. Peris, B. M. Horowitz (MITRE Corp.), A. L. MoFarland (MITRE Corp.), J. U. Beusch (Lincoln Lab., MIT), and K. D. Senne (Lincoln Lab., MIT), // AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 17 p. refs (For availability see N76-23191 14-04)

intermittent Positive Control (IPC) is a totally automated ground based collision avoidance system; it functions by taking positive control of Visual Flight Rules (VFR) and Instrument Flight Rules (IFR) aircraft on an as needed basis to avoid hazardous encounters. By also providing pilots with continuous information on the location of nearly siroraft, it results in safety in controlled, mixed, and uncontrolled airspace, among all users (air carrier, general aviation and military) in both IFR and VFR flight, while maintaining the freedom of action associated with VFR flight. To receive IPC service an aircraft must carry a Disprete Address Beacon System (DABS) transponder and an IPC display. The transponder, in addition to its beacon function, receives digital messages from the ground and presents them on the IPC display. The ground portion of the IPC system consists of the DABS sensor and an IPC computer.

FUTURE ATC TECHNOLOGY IMPROVEMENTS AND THE IMPACT ON AIRPORT CAPACITY

Richard M. Harris In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 14 p refs (For availability see N76-23191 14-04)

(Contract DOT-FA70WA-2448)

The United States is presently in its third generation of eir traffic control systems and technology. This third generation system is the first nationwide application of modern computer based technology to the management of traffic in the national alrapace system. Twenty NAS Stage A enroute installations are now in place at the domestic air route traffic control centers. In addition, 81 automated radar terminal systems are now installed and operational in the major terminal areas. Linkages between these enroute and terminal facilities are presently being established and verified. Upon completion of the installation and testing the U.S.A. will have operational a large scale, semi-automated capability to provide highly improved ATC services for domestic medium, high altitude, and terminal airapage

R76-23211 Royal Radar Establishment, Majvern (England). GROUND PECOHDANY HADAR FOR MOVEMENT

Hugh N. Griffiths In AGARD Plans and Develop for Air Traffic Systems Feb. 1976 9 p (For availability see N76-23191 14-04)

A method of using secondary radar for ground movement identification is outlined which could have sufficient positioned accuracy to label a high definition primary radar display of sirfield ground movements. An experimental ground movement secondary rader installation at an airfield site is described and the results of trials are discussed. Methods for improving the performance of the basic system are indicated and possible future developments are suggested.

N76-23212 Transportation Systems Center, Cambridge, Mass ATCRES TRILATERATION, THE ADVANCED AIRPORT SURFACE TRAFFIC CONTROL SENSOR

J. W. Ogrady, M. J. Moroney, and R. E. Hagerott. In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 20 p refs (For availability see N76-23191 14-04)

The requirements of an advanced Airport Surface Traffic Control (ASTC) system have been developed and the technology identified for the sensor part of the system. Employing Air Traffic Control Radar Beacon System (ATCRBS) replies from aircraft transponders and trilateration receivers for accurate position location and vehicle identification, the sensor system satisfies the performance and readiness requirements of intermediate (1980) goal systems. The advanced ATCRBS trilateration sensor for ASTC has been analytically established and a brassboard system is being fabricated to provide empirical validation. Author

THE CORAIL SURVEILLANCE SYSTEM FOR AIRPORT RUNWAYS [SYSTEME CORAIL DE SURVEILLANCE DE PISTES D'AEROPORT]

Jean Marc Faysse and Guy Georges Plottin (Leboratoire Control de Telecommunications) /// AGARD Plans and Develop for Air Traffic Systems Feb. 1976 18 p in FRENCH and ENGLISH (For availability see N76-23191 14-04)

The prototype CORAIL radar installed on the Paris Orly sirport runway and originally intended only for automatic runway suiveillance under conditions of poor visibility has proven itself

to be a powerful facility for controlling runway and approach corridor movements in real time, making it possible to increase the frequency of sircraft landings and takeoffs, even in clear water, whilst maintaining a high level of safety.

#76-23214 Transportation Systems Center, Cambridge, Mass. PREDICTIVE TECHNIQUES FOR WAKE VORTEX AVOID-

J. N. Halfock, W. D. Wood, and E. A. Spitzer. In AGARD. Plans. and Develop for Air Traffic Systems Feb. 1976 11 p refs (For availability see N76-23191 14-04)

Aircraft wake vortices represent a major impediment to increasing runway capacity. Separation criteria are conservative most of the time and thus traffic unnecessarily delayed by always adhering to the present inflexible regulations. Systems which employ vortex tracking sensors and/or metaorological sensors to determine safe reduced spacings are being designed. Any wake vortex avoidance strategy relies upon the ability to predict vortex transport and decay. The paper discusses vortex behavior, preliminary predictive models based upon the tracking of vortices from over 24,000 landing aircraft, and systems and their implementation to provide the capability of using adaptive separations.

N76-23215 Transportation Systems Center, Cambridge, Mass. US/UK VORTEX MONITORING PROGRAM AT HEATHROW AIRPORT

J. N. Hallock and L. Goldstone (Civil Aviation Authority, London). in AGARD Plans and Develop, for Air Traffic Systems 1976 9 p (For availability see N76-23191 14-04)

Vortices shed from sircraft landing are being recorded and analyzed and their motion correlated with ambient meteorological

conditions. It is shown that if the crosswind component measured near the runway threshold exceeds five knots, vortices linger near the extended runway centerline for a time in excess of one minute for less than 0.5 percent of the landings. This small percentage is almost entirely due to vortices from the heavy wide body jets -- the B747, DC-10 and L-1011. Author

N76-23216 Linde A.G., Munich (West Germany). FOG DISPERSAL AT AIRPORTS, THE STATE OF THE ART AND FUTURE TRENDS

W. Baldus, F. V. Malewicz (DOT, Washington, D. C.), A. Pocrnja, K. Ruppert, J. F. Sower (DOT, Washington, D. C.), and H. Wenzel In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 6 p refs (For availability see N76-23191 14-04)

Cold fog is being dispersed routinely by airborne seeding with dry ice and results show a favorable benefit to cost railo. Also ground based systems of figuld propone dispensers are used operationally for cold fog dispersal. Warm fog dispersal being more difficult has become operational at two airports of Paris. Improved prospects of economic warm fog dissipation are offered by a new heat pump system with favorable thermodynamic properties which result in an essentially lowered requirement. The artificial visibility improvement by fog dispersal systems is considered a valuable aid for safe aircraft operation under all weather conditions.

N76-23217 Federal Aviation Administration, Washington, D.C. UNITED STATES PROGRAM TO ICAO FOR A NEW NON-VISUAL APPROACH AND LANDING SYSTEM

Joseph M. DelBalzo and Stanley R. Jones (Mitra Corp., McLean, In AGARD Plans and Develop, for Air Traffic Systems Feb 1976 20 p (For availability see N76-23191 14-04)

The microwave landing system is a precision approach and landing guidance system designed to meet the needs of all types of aircraft, civil and military, throughout the world through at least the balance of this century. It is an air derived data system, i.e., ground stations will generate coded signals which will enable an airborne receiver/processor unit to derive precise azimuth angle, elevation angle, and range data, which are suitable for display to the pilot or for use by an automatic flight control system. Inherent in the MLS design is the incorporation of a ground-to-air data link which will provide runway identification. condition of runway, operational status of the MLS, and weather information. An Important element in the concept is that of performance modularity wherein a range of equipment configurations, both ground based and airborne, would be responsive to the operational requirements and economic nonsiderations of each category of user. INSTRUMENT LANDING SYSTEM PERFORMANCE PREDICTION

Gerald Chin, Lawrence Jordan, David Kahn, and Stophen Moria In AGARD Plans and Develop for Air Traffic Systems Feb. 1976 14 p. refs (For availability see N78-23191 14-04)

A physics model based on electromagnetic scattering theory has been developed for predicting comparative instrument Lending System (ILS) localizer and glide slope antennas array performance and course structure degradation resulting from a change to an airport soviconment. The theoretical predictions of the localizer model were compared with flight test data from Syracuse-Hencock airport. The agreement was good. The glide slope model has been used to predict and compare the performance of three image type antennas: The null reference sideband reference and capture effect antennas for non flat terrain configurations. It was found that acceptable course results often could be found with only one type of glide slope antenna without performing a major terrain regrading.

MEASUREMENTS OF RUNWAY VISUAL RANGE

 A. C. Stage In AGARD Plans and Develop for Air Traffic Systems Feb. 1975 11 p. refs (For availability see N75-23191 14-04)

This review of the measurement of runway visual range returns to the basic recommendation of the international Civil Aviation Organization as the basis of a fundamental appraisal of the instrumentation and system requirements. The definition of the operational requirement contains an assessment of the instrumentation task and stresses the need for representativeness in the measurement. The processes of selecting and developing the instrumentation techniques using supporting data processing are shown to provide superior system performance. Results from evaluation trails demonstrate the superior performance of an automated runway visual range system over the observer in providing operationally useful data. In conclusion, the paper discusses future requirements and instrumentation techniques for supplementary visibility assessment.

N76-23220 Federal Aviation Administration, Washington, D.C. INDEPENDENT LANDING MONITORS/SURVEY REPORT Guide Tinsley /n AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 2 p refs (For availability see N76-23181 14-04)

Continued interest over a number of years in independent landing monitor systems has resulted in proposals for widely varying techniques and devices to give the pilot a check on the primary instrument landing system and an assurance that the approach and landing is proceeding safely. An independent assessment that an approach is progressing safely have be assential for operator acceptance of approach guidance based on a single electronic signal. Current related developments are summarized to include concept, technical characteristics, and development status. For programs presently undergoing testing, a brief summary of test results is included.

N76-23222 Transportation Systems Center, Cambridge, Mass. ADVANCED AIR TRAFFIC AMANGEMENT SYSTEM STUDY

Robert H. Reck in Agard Plans and Develop, for Air Traffic Systems Feb. 1976 11 p refs (For availability see N76-23191 14./14)

Plans for the udvanced air traffic management system for the late 1980's and beyond are summarized. The plans are presented in the framework of an evolutionary system concept of traffic management building upon the upgraded third generation air traffic control system, and designed to meet the projected demands for service, safety, and flexibility in a cost effective manner. The advanced air traffic management system concept is characterized by the use of satellite to supplement ground equipment for aircraft surveillance, navigation, and communication over the United States and nearby oceanic regions; strategic

flight planning and control for flight in dense traffic regions; centralization of the control system; and a high level of automation. A program of research and development is described to provide the information needed for planning future system developments.

APPLICATIONS OF THE AIRBORNE TRAFFIC SITUATION DISPLAY IN AIR TRAFFIC CONTROL Mark E. Conneily in AGARD Plans and Develop, for Air Traffic

Mark E. Connelly In AGARD Plans and Develop, for Air Traffic Systems Feb. 1976 12 p refs (For availability see N76-23191 14-04)

The potential usefulness of displaying traffic and map information in an alteraft cookpit and the effects that the availability of such information would have on ATC procedures and capacities are evaluated. These tests indicate that the ATSD is a valuable aid to the pilot in executing the following basic functions: conflict detection and resolution, conforming to airspace structures, precise spacing in trail, merging, sequencing, monitoring runway occupancy, backup procedures after an ATC failure, approach to one of two closely spaced parallel runways operating independently, and taxling on the airport surface. A simulation study of a terminal area metering and spacing system in which computer generated commands were transmitted directly to the pilots showed that the introduction of the ATSD eliminated all violations of spacing minimums and out the dispersion of arrival times at the runway threshold in half. When the ATC generated metering and specing schedule was made available to the pilots and their flight instruments modified to assist them in executing a 4DRNAV approach corresponding to the schedule, the dispersion of arrival time errors at the runway threshold was reduced to less than three seconds.

N76-23225 Raytheon Co., Wayland, Mass. Equipment Div. A NEW SYSTEM ARCHITECTURE FOR ATC AUTOMATION

Paul E. Hamburger In AGARD Plans and Develop, for Air Traffic Systems Feb. 1975 13 p refs (For availability see N75-23191 14-04)

Automation of the National Airspace System (NAS) is well underway with both enroute and terminal control centers successfully converted to attromation. These systems are based on interfacing radar outputs to high resolution displays through one or a seclarge scale computers which provide a variety of automation functions, the most important of which are tracking controlled allocaft and formating alphanumeric data blocks for the associated aircraft. Recent studies for air traffic control systems outside the United States have shown that for applications with less concentrated traffic, a system architecture in which numerous minicomputers share the processing task, has significant advantages in cost, reliability and modularity. By being modular, the number of minicomputers required can be tailored to the size of the air traffic control center, and the computer program size can be tailored to the functional complexity warranted by the country's size, traffic level, and sophistication desired. In designing such systems, minicomputers are assigned to functions in one of two ways: either functions are subdivided and minicomputers are assinged to each subfunction, or a function performed in a similar way many times is subdivided so that several minicomputers perform the function once, or at most a few times. AERONAUTICAL EATELLITE SYSTEM (AEROSAT)
J. Ruden and J. Thomas In AGARD Plans and Develop. for Air Traffic Systems Feb. 1976 10 p (For availability see N76-23191 14-04)

An experimental aeronsutical satellite program is being undertaken on an international basis to provide a satellita system and to evaluate the ability of such a system to meat future sir traffic control requirements over oceanic regions. The reasons for undertaking such a program are outlined. The system itself is described and the principal parameters, which will be evaluated to assess performance and establish standards for any future satellite system, are discussed.

N76-23228 Messerschmitt-Boelkow-Blohm G.m.b.H., Munich (West Garmany). Human Engineering Group. MEASUREMENTS OF THE CONTROL CAPACITY OF ATC

Klaus Josehim Brauser. In AGARD. Plans and Develop, for Air Traffic Systems Feb. 1976 13 p refs (For availability see N76-23191 14-04)

Three methods of measuring the executive control load and control capacity have been developed and applied. (1) the measurement of the total time consumption of all executive control tasks generated by all a/o movements occurring in the area of jurisdiction of the executive controller. The time saturation condition indicates that the executive control load is approximating the saturation, i.e. the control capacity: (2) the measurement of a well defined partial work load which has been proved to be average constant part of the total workload, this partial work load being the R.T. channel load; and (3) controller questionnaires on estimates of their control capacity.

N76-23228 Royal Rader Establishment, Malvern (England) A MEASURING ROD FOR ATC SYSTEMS, THE INDEX OF CROERLINESS

H. Gent. In AGARD. Plans and Develop, for Air Traffic Systems Feb. 1976 8 p. refs (For availability see N76-23191 14-04)

The Index of orderliness is considered as a measuring rod for ATC systems which gives a numerical astimate of system performance at any moment of time, its calculation requires a basis for conflict prediction and a threat weighting formula. The index is then defined as a weighted count of future conflicts. The index of orderlineas/time curves produced by a collision avoidance system simulation is discussed. It is shown that such curves contain valuable information on the response time of the system. This time structure is displayed via calculation of the unitocorrelation function of an index of orderliness graph. The relation of the Index to a complete ATC system viewed as a hierarchy of control loops is presented and shown to be close. Finally it is suggested that indices of orderliness can be used to give a quantitative measure of the style of an ATC system, as well us of its performance.

Pierre Faurre and Loie Camberlein In its Pract. Aspects of

Kalman Filtering Implementation Mar 1976 42 p FRENCH, ENGLISH summery (For availability see N76-24200 15.041

Two systems using Kalman filtering are described. A hybrid inertial-Doppler-position reset navigator was studied and experimented from 1967 to 1972. The numerical algorithms were studied and implemented with care. The complete program was split into two computers, and the subprogram corresponding to the filter represented about 6,000 words, over 11,000 for the total Curves are given both for theoretical performances, and for experimental flight results. Algorithms and software for optimal alignment of an inertial platform were developed and tested from 1972 to 1974. The inertial system used for the experiment is an MGC 30. The mathematical model is quite simple, and the complete alignment program uses 1,800 words. The improvement in alignment time is quite impressive. 450 seconds for optimal alignment, to be compared to 1,031 seconds for classical alignment

N76-24208 Le Petit Monthelon, Acigne (France) A SHIP TRACKING SYSTEM USING A KALMAN-SCHMIDT

Claude A. Darmon In its Pract. Aspects of Kalman Filtering Implementation Mar. 1976 24 p refs (For availability see N78-24200 18-04)

The digital processing is described of measurements at a high accuracy ship-tracking system. The errors affecting the azimuth measurement supplied by the measuring device of the ground-bessed station are found to be the most critical for the overall accuracy of the system. A Kalman-Schmidt filter is selected for an optimum estimation of the azimuth speed, following comparisons with a Kalman filter and an averageing filter. The estimation of the navigation parameters is described and the position and speed accuracy achieved by the system is calculated. Moreover, various effects resulting from the data processing in a computer are analyzed and optimized for instance choice of the computation rate for the azimuth velocity, scaling of navigation parameters, etc. Finally, the programming of the data processing in a microcomputer is described and evaluated from two standpoints, memory space requirement and computation time. The results obtained confirm the efficiency of the solutions

N76-24207 Deutsche Forschungs- und Versuchsanstalt füer Luft- und Raumfahrt, Oberpfaffenhofen (West Germany). DESIGN AND ANALYSIS OF LOW-ORDER FILTERS APPLIED TO THE ALIGNMENT OF INERTIAL PLATFORMS Willi Kortuem In its Pract. Aspects of Kalman Filtering Implementation Mar 1976 26 p refs (For availability see N76-24200 18-04)

The typical steps and considerations for designing low-order efficient state estimators or Kulman filters are described. The design stops are demonstrated on a platform alignment problem where Kalman filtering is used rather than conventional procedures to reduce the time necessary for the required alignment accuracy The work reported is based on a test series for modelling gyro-dult and accelerometer errors. The selection of a design model for the filter, the filter design itself, and a complete covariance enalysis are emphasized. The main goal of the filter design is to achieve a simple, re , low-ont- i insensitive design.

N76-32148# Advisory Group for Assospace Research and Development, Paris (France). MEDIUM ACCURACY LOW COST NAVIGATION

Aug. 1976 387 p. refs. Presented at the AGARD Panel Tech. Meeting, Sandeljord, Norway, 8-12 Sep. 1975

(AGARD-CP-176) Avail: NTIS HC \$10.75

A total of 29 papers were presented dealing with medium accuracy low cost navigation systems for aircraft and other vehicles, by considering all the options available, so as to determine, if possible, the optimum cost/scoursey mix. These papers were divided into the following five areas: requirements and specifications, radio techniques, non-radio techniques, appropriate navigation system components, and total system considerations. For individual titles, see N76-32149 through N76-32176

N76-32149 Advisory Group for Aerospace Research and Development, Paris (France) HIGHLIGHTS OF KEY CHARACTERISTICS CONSIDERED FUNDAMENTAL TO ANY NAVIGATION BYSTEM THAT MIGHT BE INTRODUCED INTO BRITISH ARMY AIR-CHAFT

A. C. D. Watts (Brit. Army Air Corps). In its Medium Accuracy Aug. 1976 5 p (For availability see Low Cost Navigation N78-32148 23-04)

Operational factors influencing the requirement for army battlefield helicopter navigation systems are discussed and the needs of the operating crew are outlined. These considerations lead to the conclusion that a low cost, light weight, accurate. self-contained navigation system is required.

N76-32150 Royal Navy, London (England). A SURVEY OF LOW COST SELF CONTAINED NAVIGATION SYSTEMS AND THEIR ACCURACIES

J. A. Tayler In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 5 p (For availability see N76-32148 23-04)

A definition of medium accuracy and low cost is first attempted, and it is noted that air data systems do not achieve medium accuracy and inertial systems do not yet fall within the definition of low cost. Some simple truths about self contained systems are highlighted. The level of assurance at which navigation accuracies are quoted should be standardized. Doppler/compass securacy is dictated by heading accuracy overland and by surface effects over water. The basic navigation information required by the pilot is whether he should steer left or right. Investigation is required on how best to integrate navigation systems with low

N76-32161 Ferranti Ltd., Edinburgh (Sootland). THE CONCEPTION OF LOW COST NAVIGATION SYSTEMS: ART OR SCIENCE?

In AGARD Medium Accuracy Low Cost W. H. McKinlay Navigation Aug. 1976 7 p (For availability see N76-32148

Some of the factors involved in arriving at the requirement for low cost nevigation systems were pointed out. It turns out that while improvements in technology tend to reduce the costs of conventional systems, a true low cost system is probably one which is capable of extending the facilities offered by it to applications in which earlier solutions would have been declared uneconomic. The initial adoption of many of today's navigation techniques has been a result of the pressures to apply a new technology. It is suggested that in the low cost area, the corresponding pressures exerted by the market are much more significant. Most of today's devines must traditional requirements and there may be alternative solutions if the sources of information and the techniques available to handle them are related to the minimum requirements of the operator. The closest and fastest possible process of iteration between operator and system designer IS PROFESSIVE

N76-32152 Aeroplane and Armament Experimental Establishment, Boscombe Down (England). Navigation and Radio Div. MEDIUM ACCURACY LOW COST NAVIGATION SYSTEMS FOR HELICOPTERS

T.J. Penfold In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 7 p (For availability see N76-32148 23-04)

All the factors leading to a choice of a future navigation system for military helicopters were examined. The examination considers the past, the basic requirements for the navigation system, the helicopter environment, service requirement, possible systems, cost and standardization. It is concluded that a Doppler/compass system could meet the requirements for a medium accuracy/low cost system but that the requirement needs further definition especially in the areas of operational requirement and costs. It is hoped that in the future some measure of standardization be achieved, such an aim will need to be recognised and receive the goodwill of all interested parties

N76-32163 Hawker Siddeley Aviation Ltd., Brough (England). SOME NAVIGATIONAL CONCEPTS FOR REMOTELY PILOTED VEHICLES

W. Lyone, J. D. Bennister, and J. G. Brown In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 18 p. refs. (For availability see N76-32148 23-04)

Methods by which the navigation function for Remotely Piloted Vehicles (RPVs) can be achieved without the need for complex specialized navigation equipment were discussed. The objective is to make use of equipment normally carried for RPV operation to supplement a simple dead rackoning navigation system. The additional processing is carried out at the control center where restrictions on equipment size and cost are not so prohibitive.

Techniques varying from the use of the data link to provide range-bearing navigation to map matching using reconnaissance sensors or a forward looking sensor picture were discussed. Use can also be made of an on-board laser to provide range-to-terrain measurements which, when correlated with a computer stored map, enables the RPV position to be continuously updated. Results of simulation studies carried out to validate the techniques and provide an estimate of the accuracies are presented.

N76-32154 Rockwell International Corp., Anahem. Canf. MICRO-NAVIGATOR (MICRON)

Jerry A. Schwarz. In AGARD. Medium Accuracy Low Cost Navigation Aug 1976. 14 p. refs. Sponsored by the AF (For availability see N78-32148 23-04)

The Micron strapdown inertial nevigation system, developed to be a low cost medium accuracy (one nautical mile per hour radial position error CEP rate) navigation system for future aircraft/misalles requiring medium accuracy, was described. The heart of the Micron system is the micro-electrostatic gyro, which consists of a one centimeter diameter spherical rotor suspended electrostatically by eight capacitor plates. The rotor is untorqued, thus avoiding the accuracy degradation and reliability degradation from gyro torquing electronics. The gyro is used in a strapdown mechanization and utilizes a unique mass-unbalance modulation technique for obtaining whole engle readout over all attitude angles. Two bressboard Micron systems have been fabricateriand tested. The tost results indicate better performance than the one nautical mile/hr performance goal under all environments tested (laboratory, v.bration, shock, cold scak, scorsby, van, and flight test). The prototype Micron system is currently being designed, and a full evaluation test program is planned. Author

N76-32165 Draper (Charles Stark) Lab., Inc., Cambridge, Mass. DIGITAL PHASE PROCESSING FOR LOW-COST OMEGA RECEIVERS

Duncan B. Cox, Jr., William H. Lee, William M. Stonestreet, and Edwin V. Harrington, Jr. (AFAL) /n AGARD Medium Accuracy Low Cost Navigation Aug. 1976 16 p refs (For svallability see N76-32148 23-04)

(Contract F33615-72-C-1335)

The application of the serial digital phase filter (SDPF) to Omage receiver is explored. It is shown that the internal functions of an Omega receiver can be organized to take advantage of one or more SDPF's used in combination with an LSI microprocessor. The SDPF's can also be used to reduce the load on the microprocessor by reducing the bandwidth of the phase data being presented to it. The SDPF's can also accomplish demodulation and enalog-to-digital conversion, thereby eliminating the need for special circultry to perform these functions. Because of the reduction in date bandwidth, thore is an increase in efficiency and productivity of the microprocessor. The processing efficiency of the entire receiver is then more closely maximized with respect to hardware and software cost. The design approach is applicable to a bare-bones receiver, which would incorporate the most elementary and inexpensive microprocessor or no microprocessor at all

N73-32156 ITT Avionics, Nutley, N.J.

LOW COST NAVIGATION PROCESSING FOR LORAN-C AND OMEGA

James F DeLorme and Arthur R Tuppen /n AGARD Medium Accuracy Low Cost Navigation Aug. 1976 17 p (For availability see N76 32148 23-04)

A technology feasibility demonstration was performed to determine the impact of advances in MOS/LSI semiconductor developments on performance and cost of radio navigation equipment, in particular, Loren C performance amd cost objectives were demonstrated. This demonstration has clearly shown that the performance requirements for both austere and sophisticated users can be satisfied. Advancement in semiconducfor technology has provided MOS/LSI and Schottky Bi-Polar/LSI chip sets, central processor units and compatible semiconductor memories, whose architecture is compatible with the requirements for navigation processing. This technology has been applied to a Loran C sensor processor and a low cost airborne Omega Navigator. The digital processing, micro-computer configuration, resultant performance and cost projections for Loran C applications are described. The results of the mechanization for these systems are used to configure a combined Loran C or Omega Navigator. including an assessment of performance parameters, physical characteristics and costs projections

N76-32167 Naval Electronics Lab Center, San Diego, Calif A NAVIGATION MONITOR FOR VLF SIGNALS

E.R. Swaison In AGARD. Medium Accuracy Low Cost Navigation Aug. 1976. 7 p. refs. (For availability see. N76-32148-23-04).

An overview of the need for and the design of a VLF navigation monitor is presented Fundamental associated with various VLF navigational techniques are discussed briefly. 2-nulle accuracy or better is assumed typical. Sale operation within existing airways is normally possible, but protection against propagationally induced blunders should be provided by a navigation monitor. The monitor can be designed so as to provide not only disturbance warning but also disturbance prediction. The monitor can also assist in preflight.

N75-32158 Standard Electrik Lorenz A.G., Stuttgart (West Germany)

SOME CONSIDERATIONS ON POSSIBLE NEW VHF LOW COST RADIO NAVIGATION AIDS

COST RADIO NAVIGATION AIDS

M. Brohm In AGARD Medium Accuracy Low Cost Navigation

Aug. 1976 16 p. refs (For availability see N76-32148 23-04)

New possibilities for low cost navigation aids for use in allocated VHF communication frequency bands are described Conventional VHF radio sets are to be useable also for navigation by adding a simple attachment. Three system proposals are presented (1) The ship navigation system SNS is to use shore attations simploying either amplitude or frequency modulation. It would provide 0.1 deg error azimuth within a sector of e.g. 10 deg and 3.5 deg error azimuth within a sector of e.g. 10 deg and 3.5 deg error ominiangle azimuth. (2) The ship identification and location system SILOS is to employ a chain of shore based VHF DF stations which determine positions of ships by biangulating their communications transmissions. (3) The hyperbolic navigation system HNS for tactical applications is to use a chain of VHF stations transmitting synchronized modulation frequencies used for navigation. The coordinates of the highly mobile stations can be transmitted to the users continously in a coded form Expected accuracy is 50 m CEP.

CONTINUOUS NAVIGATION UPDATING METHOD BY

MEANS OF AREA CORRELATION

A. Hessel and W. Eckl. In AGARD Medium Accuracy Low
Cost Navigation. Aug. 1976. 19 p. refs. (For availability see
N76-32148 23-04)

An autonomous automatic updating method is considered for the improvement of navigation accuracy. This is based uponthe correlation between an instantaneously taken picture and a stored scene of the area of interest. The displacement between the actual position and the indicated position (taken from the simple basic system) is derived from the maximum crosscorrelation of the two pictures. Results of different correlation-algorithms applied to microwave images of different sizes and scene complexity (groy values) are shown. Topics for further research work necessary before flight testing such a system are outlined.

N78-32160 Wenshipugh-White and Co. Ltd. Lon. (England. GRAPHIC AREA NAVIGATION WITH VOR/VOR, AND VOR/DME INPUTS

G. Wansbrough-White In AGARD Medium Accuracy Low Cost Navigation Aug 1975 17 p (For availability see N76-32148 23-04)

The following conclusions relative to some papers of graphic analogation were given and discussed. (1) area nevigation offers advantages of safety and economy to both arrines and general aviation, with advantages to air traffic control. (2) area nevigation must dispend on corrivational DR methods, with and without radio, in the low cost area of general eviation. There are pilot/nevigator problems, and one development has been the airborne course line computer ("ghost VOR"). (3) another development is Graphic Area. Navigation (GRNav), which uses standard VOR. DME (and other inputs), and is a computer based cartesian system that is self-checking and geographically oriented. (4) GRNav has airways and marine applications. (5) GRNav has been shown to be a practical, simple and cheap navigation system, and is now subject to scientific evaluation in the UK and the USA.

N76-32161 Office National d'Etudes et de Recherches Aerospatiales, Paris (France)

INEXPENSIVE SYSTEM OF MULTIPLE BEACON LOCALIZA-TION FOR HELICOPTERS Jacques Dorey In AGARD Medium Accuracy Low Cost Navigation Aug 1976 9 p. refs. In FRENCH, ENGLISH summary (For availability see N76-32148 23-04)

Two systems of angular (elevation and azimuth) localization of multiple beacons, for application to helicopters, are pre-2 system making use of the helicopter blades as receiving dipole support, in association with UHF emitting beacons.

a system making use of an independent rotating arm as dipole support, placed under the helicopter fuselage, in association with microwave emitting beacons. The first system is analyzed in detail, limitations of various kinds are emphasized, in particular those concerning the working wavelength. The data processing devices leading to the electromagnetic imagery of the beacon angular distribution are described. The second system, less applicable to helicopter, is presented and compared to the first one as repards its performance

N76-32162 Naval Weapons Center, China Lake, Calif THE APPLICATION OF RING LABER GYRC TECHNOLOGY TO LOW-COST INERTIAL NAVIGATION

William F Bell In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 16 p (For availability see N76-32148-23-04)

The Advanced Tactical Inertial Guidence System (ATIGS), a strapdown system using Ring Laser Gyros (RLGs), low-cost accelerometers, and large-scale integrated circuitry computer technology, was described. Although primarily developed for a long-range tactical missile application, the system mechanization that has evolved is directly applicable to aircraft inertial navigation. The first ATIGS unit entered captive flight evaluations in a pod on a A-7E aircraft on 20 June 1974. Results achieved during this first series of tests showed approximately 4 nmi/hr radial error. In March 1975, ATIGS was flight-tested as an aircraft navigator, with ground self-alignment and with flight times of 3 to 4 hours. In these tests an average circular error probable radial error of 2.16 nmi/hr was obtained. The Ring Laser Gyro RLG appears to offer a truly low-cost alternative for future alreraft mertial navigation based on the results of the ATIGS program. Further ATIGS results have indicated that excellent long-term stability can be expected from these unconventional instruments. These factors indicate that, if properly integrated with low-cost accelerometers and appropriate low-cost digital computers, a medium-accuracy, low cost inertial navigator is possible. Author

INERTIAL NAVIGATOR FOR COMMERCIAL AIRLINES Julius Weiss In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 11 p refs (For availability see N76-32148 22-04)

The GAMMA Advanced Inertial Navigation System is an outgrowth of the SKN-2400 family of military inertial navigation equipment, and hence represents the present state of the art in advanced electronic packaging. The development of the GAMMA Advanced Inertial Navigation System, its physical and functional description and its impact, specifically on smaller general aviation aircraft, are described. The development of the system was completed after many months of qualification and flight testing under the eegls of the Federal Aviation Administration (FAA) The details of these tests and their results are provided. Author

N76-32164 Teledyne Ryan Aeronautical Co., San Diego, Calif. LIGHTWEIGHT DOPPLER NAVIGATION SYSTEM Robert E. Chapman In AGARD Medium Accuracy Low Cost Navigation Aug. 1978 22 p (For availability see N76-32148

A self contained, low cost, lightweight, accurate, and reliable navigation system for military helicopters was designed. The system consists of a Doppler Radar Velocity Sensor (DRVS) and a Computer Display Unit (CDU) with a combined mean time difference between failures of more than a 1000 hours, and a 38 percent circular error probability. The capability of the system to be integrated with radio-aided navigation systems such as LORAN and OMEGA is described. An important feature of the system is the capability of rapidly isolating failures to a replacable module, and ease of replacement of the 'failed' module The use of a special modulation form in the DRVS to develop a coherent local oscillator is described. Also described is an IMPATT solid state transmitter, time duplexed travelling wave array antenna, and digital frequency tracker. Use of a single chip microprocessor in the CDU is described; emphasis on the human factors engineering aspects of the man-machine interface. Results indicate that system meets the requirements that it was designed

N76-32165 Singer Co., Wayne, N.J. DOPPLER HADARS FOR LOW-COST, MEDIUM ACCURACY **NAVIGATION**

Heinz Buell In AGARD Medium Accuracy Low Cost Navigation Aug 1976 10 p (For availability see N76-32148 23-04)

A Lightweight Doppler Navigation System (LDNS) was designed which weighs under 30 pounds and has a predicted mean time difference between failures of over 1400 hours and a predicted navigation accuracy of 1.3% of distance travelled with 1% (1 sigma) heading reference. The system is designed for use in military helicopters. The LENS consists of four units (1) Doppler radar velocity sensor, consisting of a receiver transmitter antenna unit and signal data converter unit. (2) control display unit, and (3) steering hover indicator unit. Diagrams Illustrating each unit are shown.

N76-32166 Ferranti Ltd., Edinburgh (Scotland)
TWO NEW SENBORS AND THEIR POSSIBILITIES IN LOW
COST HEADING REFERENCE SYSTEMS

W. H. McKinlay, A. Liebing, and K. R. Brown In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 7 p (For svallability see N76-32148 23-04)

The requirement for heading in a navigation system, both as primary data and for the pointing of certain sensors is discussed. The airborne applications of heading for fixed and rotating wing aircraft are examined it is pointed out that developments in gyroscopes, resulting from inertial technology, now make it possible to provide a heading memory with a very low drift. But this is not usable unless the device can first be referenced to true North, which introduces the desirability of gyra-compassing. This, in turn, leads to certain instrument requirements. Two new sensors suitable for use on gimballed platforms but assentially of simple construction and relatively low cost. They are Double Integrating Angular Accelerometer and a Free Rotor Gyroncope. the Oscillogyro. Possible system configurations are indicated, and conclusions are drawn as to areas in which these techniques can most profitably be applied.

LOW COST SELF CONTAINED SOLUTIONS TO THE NAVIGATION PROBLEM IN ROTARY AND FIXED WING E Brewin (Decca Co. London), T.S. Kitching (Decca Co., London), and D. L. Wright. In AGARD Medium Accuracy Low Cost Navigation. Aug. 1976. 11 p. (For availability see N76-32148 23-04).

Defense budget limitations often make it necessary for the operational staff of many air forces to review their avionics system requirements. Only limited reliance can be placed on the use of ground based radio aids while the high cost pure inertial solution far from satisfies the multiplicity of military aircraft roles with which the operational stalls have to contend. A Modular Building Block Concept for self contained systems is proposed which can be tailored to provide the required facilities and performance to meet a specific role while retaining a high degree of logistic commonality between differing aircraft types, and at a low cost. The proposed modular solution, already a fact with hardware in production and going into service is based upon the use of the following hardware elements. (1) a two/three axis velocity sensor, (2) a two/three axis heading/attitude sensor, and (3) a digital navigation computer. The possibility of coupling of these systems to a range of weapon delivery equipment is suggested

HAND HELD CALCULATOR TECHNOLOGY APPLIED TO AN
ADVANCED LOW COST OMEGA RECEIVER

Bernard N. Gaon. In AGARD. Medium Accuracy Low Cost Navigation Aug. 1976. 9 p. rnfs (For availability see N76-32148 23-04)

Recent technological advances in metal oxide semiconductor circultry have resulted in mass production of commercial calculators and with it the availability of low cost microprocessors. These devices, although limited in computational capability, can be successfully applied to the development of a low cost Omega navigation set. The basic desirable features of an airborne Omega receiver were studied, and the required functions identified. A simplified technique to achieve better accuracy was identified. The ways in which microprocessors can be utilized to arrive at a low cost, fully automatic composite airborne system are outlined. The receiver and processor portions of the Omega set are detailed Prototype hardware that has been flight tested is described, and performance data are presented. The basic function of the Omega set is to determine and keep track of present position by receiving and processing the Omega very low frequency transmissions. Photographs of the control and display units of the Omega set are provided.

THE APPLICATION OF MINI-PROCESSORS TO NAVIGA-TION EQUIPMENT

M. R. Hopper In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 11 p (For availability see N76-32148 23-04)

Modern technology has allowed the production of a very small ministure processor using integrated circuit techniques. Because of it's simplicity and size, the same processor can be used variously, to process information from a variety of different inputs, to provide information to drive various output peripherals, or to process information within a duclosted equipment. The design requirements for, and the operation of such a mini-processor are considered. It's uses are illustrated by it's inclusion in a piace of dedicated navigation equipment (TACAN), where it is used to solve a particular set of data. Also it is considered in a family of area navigation systems, where it's flexibility is illustrated by the varying requirements of such systems. Photographa of display devices, digital computers and other components used are shown.

SYSTEM APPROACH TO PRACTICAL NAVIGATION

Jin W. Chin and Russell E Weaver, Jr. (Northrop Electronics Div.) In AGARD Medium Accuracy Low Cost Navigation Aug. 1976, 14 p. refs (For availability see N76-32148 23-04)

A background introduction is presented of various navigation sensors discussing their characteristics and limitations forthcoming satellite navigation system, NAVSTAR Global Positioning System (GPS), will be exploited as an ultimate capability of providing L Band signals from which positic-, velocity, and time can be determined. This dual capability will simplify the implementation of integrated systems. A typical medium accuracy system is described. The widely accepted inclusion of an inertial subsystem will be emphasized on the merit of a multifunctional capability beyond that for navigation. Roles in flight control, instrumentation, and augmentation of mission avionics are recognized. The strapdown mechanization and associated instruments are introduced to discuss a potential alternative to the conventional all stitlude, gimballed platform. These advances provide the attributes to accomplish low cost designs of medium accuracy navigation systems. Integration of available sensor data to provide the required navigation performance is considered the most effective method of attaining low post equipment. Modularity expressed in the design will provide flexibility and adaptability to a broad class of usors. A total performance, costs of ownership, approach is used to verify system design and selection. Author

INTEGRATED DOPPLER/HEADING REFERENCE/RADIO NAVIGATION

D. Halliwell In AGARD Medium Accuracy Low Cost Navigation Aug. 1976 9 p. (For availability see N76-32148 23-04)

Medium accuracy low cost navigation systems provide flexibility of operation with the minimum of fimitations, while retaining the major benefits of simplicity of concept and of clesign. A simple system concept based on currently available equipments is outlined. A DR system based on a currently available gyromagnetic heading reference and a fixed-serial Doppler rader is assessed as capable of two sigms accuracy in the range 1% to 3% of distance flown. For operations requiring consistent accuracy over long periods of flight or accurate relative navigation the DR system is supplemented by a simple Omega raceliver front-end, the signals being processed in the DR system computer. The system is capable of providing medium to high accuracy navigation at low total cost for a wide range of helicopter and alroraft operational requirements.

AN OPTIMALLY INTEGRATED PROJECTED MAP NAVIGA-TION SYSTEM

D. B. Reid, R. K. Harman, and D. J. Frame. In AGARD. Medium Accuracy Low Cost Navigation. Aug. 1976. 31 p. refs. (For availability see N76-32148-23-04)

A unique integrated tactical navigation system (ITNS) concept for helicopter applications is described. This concept, which could be extended for application in high performance factical aircraft, is based on the projected map system. PMS E-8, currently in production. The primary navigation unit of the ITNS is the Doppler dead reckoning (DR) subsystem which uses simple directional

and vertical gyros as heading and attitude sensors. Auxiliary navigation data are supplied by a projected map display (PMD) and a triad of magnetometers strapped to the airframe. The PMD displays aircraft position, track and bearing to destination pictorially, providing excellent pilot prientation and position fixing capability. The magnetic sensor measures three components of the earth's field, from which additional heading and attitude information are derived. A digital Kalman filtering algorithm is implemented to estimate system errors from DR, PMD and strapdown magnetic data. The error estimates are fed back to correct DR position and null sensor errors, resulting in a fully integrated system which provides excellent performance at low cost. Simulation results indicate that system accuracy without position fixes will be better than 2 per cent of distance travelled (95 per cent confidence).

A symposium was held at Eglin AFB, Florida which govered the following main topics. (1) system development techniques, (2) navigation and control technology, (3) terminal phase technology, (4) precision weapon concepts, and (5) system evaluation, and research and development program needs.

X77-72036 Advisory Group for Aerospace Research and Development, Paris (France). USE OF PRECISION POSITIONING SYSTEMS BY NATO.

VOLUME 1

Jul. 1978 48 p

(AGARD-AR-88-Vol-1) Avail: Advisory Group for Aerospace Research and Development, Paris, France NATO-Classified report

NOTICE: Available to U.S. Government Agencies.

An evaluation of the potential applications within NATO of a precision positioning system (PPS) - as exemplified by the U.S. NAVSTAR Global Positioning System - is presented. Special emphasis is placed on a qualitative and quantitative evaluation of the impact of increased position information accuracy on the tactical air attack capability of NATO in Europe in the 1980's and beyond. The study concludes that a secure and very precise PPS is feasible. With such a system, the all-weather attack capability on quasi stationary targets is to promising that continuing operational analysis should be performed

X77-72042 Advisory Group for Aerospace Research and Development, Paris (France). NIGHT VISION DEVICES FOR FAST COMBAT AIRCRAFT [1975] 624 p

(AGARD-H-73; AASC-Study-5) Avail-Advisory Group for Aerospace Research and Development, Paris, France NATO-Classified report

NOTICE: Available to U.S. Government Agencies.

The application of night vision devices to fast combat aircraft operating at low altitudes is considered from the standpoint of synthesizing and analyzing overall systems for attacking typical

ground targets. The effects of terrain screening, weather, human factors and display problems, target characteristics with the main emphasis on vehicles, navigation accuracy, and aircraft attack dynamics for the case of retarded bombs are examined. Shortfall in knowledge in key areas is highlighted, principally the importance of atmospheric attenuation on FLIR purformance, the degradation in human operator performance in turbulent conditions at low altitudes, and the interaction of pensor/display parameters with severe search time constraints. The impact of a threat environment was deliberately excluded

AN OVERVIEW OF US ARMY HELICOPTER STRUCTURES RELIABILITY AND MAINTAINABILITY

Thomas L. House (Army Air Mobility R and D Lab., Fort Eustis, Va.) Jan. 1974 19 p. refs. Presented at 36th Meeting of the Structures and Mater. Panel (SMP), Milan, 2-5 Apr. 1973 (AGARD-R-813) Avail: NTIS. HC \$4.00

Approximately 25 percent of all U. S. Army helicopter failures and field maintenance man hours are related to structures. Externally induced damage is the primary cause of many failures. and it is the essential reliability and maintainability consideration in the selection of rotor blade and transparency designs. With the exception of rotor blades, most structural failures are normally considered as maintenance downtime sensitive as opposed to a cost problem. Greatly improved design and test documents coupled with lessons learned appear to be "he most responsive approach to gaining significant structural improvements. Helicopter vibration reduction can produce a major reduction in secondary structural failure and maintenance rates.

TECHNICAL EVALUATION REPORT ON AGARD FLIGHT MECHANICS PANEL SYMPOSIUM ON FLIGHT IN TURBU-

W. S. Alken, Jr. (NASA), Washington) and D. Lean (Roy, Aircraft Estab., Redford, Engl.) Feb. 1974 10 p Conf. held at Woburn Abbey, Engl., 14-18 May 1973 (AGARD-AR-67) Avail: NTIS HC \$4.00

The proceedings of a conference on the effects of atmospheric turbulence on flight characteristics are presented. The subjects discussed include the following: (1) turbulent environment, (2) operational problems, (3) design criteria, and (4) artificial aids for flight improvement. One conclusion is that there is a critical need for cross correlation measurements between various low atmosphere turbulence components. Additional discussion were held concerning wake vortex research for wake vortex detection and avoidance.

N74-26445# Advisory Group for Aerospace Research and Development, Paris (France) PREDICTION METHODS FOR AIRCRAFT AERODYNAMIC CHARACTERISTICS

May 1974 349 p refs (AGARD-LS-67) Avail: NTIS HC \$20.50

The proceedings of a conference on methods of predicting aircraft performance are presented. Emphasis was placed on predicting aircraft range and radius, sirfield and maneuver performance, and serodynamic characteristics. Combat and transport aircraft were considered over conditions ranging from axtremely low speeds through subsonic/transonic to supersonic speeds. Aircraft lift and drag estimation methods were analyzed along with related aerodynamic optimization techniques. Practical methods for wing/body serodynamic design and boundary layer flow treatments were considered. The prediction and implications of special serodynamic characteristics associated with engine installation and external store effects are examined, relevant stability/control needs are reviewed, and some aircraft noise restraints on serodynamic design are investigated. For individual titles, see N74-26446 through N74-26455.

N74-26446 Royal Airgraft Establishment, Farnborough (England). GENERAL TECHNICAL INFORMATION John Williams In AGARD Prediction Methods for Aircraft

Aerodyn Characteristics May 1974 5 p (For availability see

Prediction and optimization methods for determining aircraft performance are discussed. The major deficiencies in the state of knowledge on aerodynamic characteristics are assessed. Recommendations for improvement in theoretical treatments, ground based testing facilities, and flight testing techniques are aubmitted. The overall technical constraints on aircraft performance

prediction are defined. Specific technical lectures on the subjects of aircraft performance, wing serodynamic design, engine installation perodynamics, external store serodynamics, and stability and control implications are identified. Author

N74-26447 McDonnell-Douglas Corp., Long Beach, Calif. Aerodynamics Subdivision. AERODYNAMIC PREDICTION METHODS FOR AIRCRAFT AT LOW SPEEDS WITH MECHANICAL HIGH LIFT DE-

VICES J. G. Callaghan In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics. May 1974, 52 p. refs (For availability see N74-26445 16-021

A survey of present methodology used for the estimation of low speed serodynamic characteristics of sircraft with mechanical high lift systems is presented. While this methodology is applicable to a large variety of sircraft with unpowered high lift systems, the emphasis is on transport type aircraft. Prediction methods empirically derived from experimental data, as well as more sophisticated theoretical methods are discussed. Correlations of calculated results with both wind tunnel and flight measurements are presented. To place the current state of the art of methodology into proper perspective, a critical review of areas of both strength and weakness is presented, with emphasis on future requirements. Within this context, the particular need for methods to estimate the high lift characteristics of aircraft with thin, highly swept. low aspect ratio wings, such as supersonic transport configurations are reviewed.

N74-26448 Royal Aircraft Establishment, Sedford (England). A REVIEW OF THE LOW SPEED AERODYNAMIC CHARAC-TERISTICS OF AIRCRAFT WITH POWERED LIFT SYS-TEMB

D. N. Foster In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics May 1974 43 p refs (For availability see N74-26448 16-02)

The serodynamic characteristics of a number of different configurations of fixed-wing aircraft with powered lift systems are discussed. Methods for predicting the serodynamic characteristics are developed. Consideration is given to aircraft employing boundary layer control, based on jet flaps with internal blowing. external blowing from underwing and overwing engines, and augmentor systems. Spanwise blowing and other specialized techniques are examined. Aerodynamic characteristics in ground effect, as well as in free sir, are reported. Some aspects of the noise problems which are directly related to the particular lowered lift system under discussion are considered.

N74-26449 Bosing Commercial Airplane Co., Renton, Wash. AIRCRAFT LIFT AND DRAG PREDICTION AND MEASURE-MENT

G. M. Bowes In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics May 1974 44 p refs (For availability see N74-28445 16-02)

Techniques for predicting and measuring lift and drag relationships for subsonic cruise flight are described. The status of this drag methodology is reviewed. Recent presentations on the subject are referenced and incorporated into an overall summary describing current capabilities for developing the basis of alteraft performance predictions. The role of the wind tunnel in airplane design and development is discussed, and the importance of flight test measurements of specific range and engine parameters is emphasized. Theoretical developments for three-dimensional design and lift/drag predictions are described. The accuracy with which the drag levels of a new design can be determined is examined. Examples of specialized wind tunnel and flight investigations into the airflow and pressures on localized portions of an airplane are presented.

PREDICTION OF SUPERSONIC AIRCRAFT AERODYNAMIC CHARACTERISTICS

C. S. Leyman and T. Markham In AGARD Prediction Methods for Aircraft Aerodyn, Characteristics May 1974 52 p. refs (For availability see N74-28446 16-02)

The methods currently available for the prediction of the aerodynamic characteristics of supersonic aircraft as they effect performance are reviewed. The problems of supersonic aircraft

the state of the s

design are illustrated by consideration of hypothetical transport and flighter sircraft. The methods used to predict the performance of the Concorde aircraft are stressed. The aerodynamic principles which make supersonic sircraft different from subsonic designs are analyzed. The accuracy and suitability of design methods for various stages of design are examined. The state of the art for estimating parisitic drag and thrust loss due to air leakage is described. Problems of estimating the installed powerplant performance are included.

N74-26451 National Aerospace Lab., Amsterdam (Natherlands). APPRAIRAL OF WING AERODYNAMIC DESIGN METHODS FOR SUBBONIC FLIGHT SPEED

W. Loeve In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics May 1974 41 p refs (For availability see N74-26445 16-021

For a number of direct calculation methods for the prediction of flows around wings at subsonic speed, the basic assumptions are discussed. This forms the basis for the applicability of the methods. Cumparison of calculated pressure distributions with results from wind-tunnel tests serve to illustrate this for three-dimensional wings and for the limiting case of plane flows around airfolis. Attention is paid to the use of inverse methods. In this context the use of hodograph methods for the design of aerofolis with transonic shockfree flow is discussed. Author

ROUNDARY LAYER CALCULATION METHODS AND APPLICATION TO AERODYNAMIC PROBLEMS

J. Steinheuer In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics May 1974 48 p refs (For availability see N74-26445 16-02)

Methods for analyzing boundary layer flow characteristics and application to predicting aircraft performance are discussed. Mathematical models for a steady two-dimensional incompressible boundary layer are developed. The structures of the various types of boundary layers are enalyzed. Tables of data are included to show the numerical solution of partial differential equations for different flow conditions. Examples of boundary layer calculations are included for cases of compressible boundary lavers, three dimensional boundary layers, and turbulent boundary layers. Airfolls are examined for conditions of attached flow over a single airfoli, attached flow over an airfoll with a slotted flap. and sirfoll flow with separation. Methods for predicting buffet boundaries for a wing in transonic flow are reported.

N74-26453 Office National d'Etudes et de Recherches Aerospatiales, Paris (France).

ENGINE INSTALLATION AERODYNAMICS

J. Laynaert In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics May 1974 22 p refs (For availability see N74-26445 16-02)

Aspects of engine installation scrodynamics are considered to include theoretical design, optimization of the engine installation, and experimental study. Air intake, afterbody, and engine/aircraft integration problems are analyzed for high subsonic and supersonic sircraft. High speed and low speed performance are discussed. Comments are made on variable geometry devices. Special attention is given to the significance of the various propulsion and drag balance terms.

N74-26464 Aircraft Research Association, Ltd., Bedford (England).

EXTERNAL STORE AERODYNAMICS FOR AIRCRAFT PERFORMANCE PREDICTION

J. B. Berry In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics May 1974 34 p refs (For availability see N74-26445 16-02)

Some effects of external stores on the serodynamic characteristics of aircraft and in particular the incremental drag due to various types of store installation are described. Examples of drag increments for single and multiple store assemblies installed underwing and underfuselage and the effects of C sub L and Mach number up to high subsonic speeds, illustrate some of the interference features in the aircraft-store flow field which contribute to high or low drag. The prospects for incremental drag prediction, the possible use of calculated or measured flow field data, empirical methods and flight-tunnel comparisons are discussed. Approximate empirical estimation procedures for simple underwing and underfuselage store installations are described. It

is suggested that for multiple store assemblies, opportunities for drag reduction offer considerably more promise than attempts to predict the drag ingrament. Significant drag savings are demonstrated not only for new types of installation but also by relatively simple modifications to existing designs.

N74-26455 Royal Aircraft Establishment, Farnborough (England). SUPPLEMENTARY CONTRIBUTION ON AIRCRAFT PER-FORMANCE CONSIDERATIONS FOR NOISE REDUCTION John Williams In AGARD Prediction Methods for Aircraft Aerodyn. Characteristics May 1974 1 p (For availability see N74-26445 16-02)

The problem of achieving much lower noise levels outside sirport boundaries, while at the same time predicting and quaranteeing the noise field from future aircraft with greater accuracy, is examined. Methods for obtaining reductions in alreraft noise levels are identified. The integration of aircraft performance characteristics, sirframe design, and sirframe-engine sero-acquatic intereference parameters to produce reduced noise tovels is emphasized.

THE ROLE OF PRELIMINARY DESIGN IN REDUCING DEVELOPMENT, PRODUCTION AND OPERATIONAL COSTS OF AIRCRAFT SYSTEMS

William E. Lamer In AGARD Aircraft Design Integration and Jun. 1974 7 p (For availability see Optimization, Vol. 1 N74-31458 21-02)

Methods for reducing the development, production, and operational costs of alicraft systems through preliminary design procedures are discussed. The manner in which the preliminary design process is conducted in analyzed. The critical program decisions which are made on the basis of the preliminary design process are identified. The preliminary process is further defined to show the application for assessing the payoff of technical innovations and emerging technologies on system capabilities. Diagrams are provided to show the preliminary design flow chart, system program phases, preliminary design process uses, and dost reduction methodologies. Author

N74-31460 General Dynamics/Fort Worth, Tex. PRELIMINARY DESIGN ASPECTS OF DESIGN-TO-COST FOR THE VF-16 PROTOTYPE FIGHTER

William C. Diatz /n AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 18 p (For availability see N74-31458 21-02)

Methods for reducing the development costs of the YF-16 aircraft are discussed. The YF-16 prototype aircraft was conceived and is being developed as a low-cost, exceptionally high-maneuvering-performance fighter aircraft. To meet the cost/ performance objectives, a number of advanced technology features, including vortex lift, variable wing camber, wing/body blending, relaxed static stability/fly-by-wire, and high-performance normal-shock inlet, were optimized and integrated during the preliminary design phase. The basic design concept was to apply these advanced technologies in a way, first, to produce a small-size aircraft and, second to achieve simplicity - both of these design objectives having a direct beneficial effect on the development, acquisition, and life-cycle cost. The resulting configuration is predicted to meet all program cost/performance objectives.

N74-31462 Douglas Aircraft Co., Inc., Long Beach, Calif. CREATIVE ADVANCED DESIGN: A KEY TO REDUCED LIFE-CYCLE COSTS

Richard E. Black and John A. Stern *In* AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 13 p. refs (For availability see N74-31458 21-02)

Advanced design decisions with an impact upon the life cycle costs of aircraft systems are discussed. The impact of advanced design decisions commences during the detail design and development phases, continues into the production phase and becomes a dominant factor during the operational life of the aircraft system. Even for a well defined mission there are many factors bearing on costs that must be considered during the advanced design phase. Several of these have been selected for examination: (1) the number of engines to be used, (2) selection of equipment and systems, (3) the simplification of design, (4) the materials to be used, and (5) the level of avionics sophistication. These advanced design decisions cannot be made solely from a technical or cost standpoint, but must consider the operational environment in which the aircraft system will function as well as the demands of the market place. There are strong indications that the more intense the advanced design effort the lower will be the detailed design, manufacturing and development costs as well as life cycle costs. During the advanced design phase, it is extremely important that the critical wind-tunnel tests be performed to avoid costly redesign after the detailed design drawings have been released. The contribution that creative Advanced Design makes to the development of effective aircraft systems has greatly increased as the result of rising costs. Errors in judgement are now more costly then ever before

N74-31463 Office National d'Etudes et de Recherches Aeronautiques, Paris (France).

CRITICAL ANALYSIS AND LABORATORY RESEARCH Work at the Stage of Aircraft Preliminary Design

Claude Lievens and Philippe Poisson-Quinton In AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 26 piet in FRENCH: ENGLISH summary (For availability see N74-31456 21-02)

The requirements to be met by a research laboratory in preparation for the preliminary design phase of sophisticated aircraft development are analyzed. It is stated that the research center must forecast the main trends of aeronautical techniques in order to provide the government services and the constructors with a maximum of information. The required actions of the government techniques services are defined to include. (1) generation of preliminary studies for contractor use. (2) to begin basic research studies. (3) to identify technical risks, and (4) to monitor the progress of works under development and reorient the effort where required.

N74-31464* National Aeronautics and Space Administration Arres Research Center, Moffett Field, Celif. COMPUTERIZED PRELIMINARY DESIGN AT THE EARLY STACES OF VEHICLE DEFINITION

Thomas J. Gregory In AGARD Alroralt Design Integration and Optimization, Vol. 1 Jun. 1974 8 p. refs (For availability see N74-31458 21-02) CSCI 018

The conceptual and preliminary design processes are used to provide information regarding the fessibility and selection of

various approaches to strotaft mission requirements. Decisions influenced by this information often have enormous cost implications at the later stages of the development process and during vehicle operation, yet the resources expended during the sarly phases are usually relatively small and distributed over several alternate approaches. The information provided during these early conceptual and preliminary design phases needs to be credible and complete, even though it must be generated with limited resources. Criteria for acceptance of early design information, modern methods of providing it and suggestions for defining adequate levels of resources to accomplish the objectives of the activity are described. Specific examples of the most difficult type of early design studies, which are those requiring significant undeveloped technology, are used to discuss these points. The examples include design studies and dost estimates of liquid hydrogen fueled aircraft, oblique winged aircraft, and remotely piloted vehicles.

N74-31485 Vereinigte Flugtechnische Werke-Fokker G.m.b.H., Bremen (West Germany). PRELIMINARY DESIGN TECHNIQUES FOR UNMANNED, REMOTE PILOTED VEMICLES

R. Staufenbiel and H. Schmidtlein /n AGARO Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 14 p (For availability see N74-31458 21-02)

The steps involved in the design of remotely piloted vehicles are discussed. Specific areas of concern are: (1) combat tactics, (2) weapony, (3) sensors, (4) payload and range, (5) guidance and control, and (6) maintainability, storability, and vulnerability. The characteristics of a typical RPV are analyzed to provide an example of the important factors which are involved in the design procedure.

N74-31467 Bueing Commercial Airplane Co., Seattle Wash. DESIGN EVOLUTION OF THE BOEING 2707-300 SUPER-SONIC TRANSPORT. PART 1: CONFIGURATION DEVELOPMENT, AERODYNAMICS, PROPULSION, AND STRUCTURES

W. C. Swan In AGARD Arcraft Design Integration and Optimization, Vol. 1 Jun. 1974 18 p (For availability see N74-31458 21-02)

The design activities involved in developing the Boeing 2707 supersonic transport sicraft are discussed. The history of the design activity is presented to show areas where failure and/or misconception occurred due to insufficient knowledge and to show how the shortcomings were corrected or avoided in subsequent configuration evaluations. Emphasis is placed on selected areas where preliminary design tools could be improved. The various design configurations are illustrated and their technical features are analyzed. The structural design features of various components are described and illustrated. The operational objectives on which the preliminary planning was based are defined. The functions of specific segments of the organization. Author Authors.

N74-21468 Boeing Commercial Airpiene Co., Seattle, Wash. DESIGN EVOLUTION OF THE BOEING 2707-300 SUPER-BONIC TRANSPORT. PART 2: DESIGN IMPACT OF HANDLING QUALITIES CRITERIA, FLIGHT CONTROL SYSTEM CONCEPTS, AND AEROELASTIC EFFECTS ON STABILITY AND CONTROL

W. T. Kehrer In AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 10 p refs (For availability see N74-31458 21-02)

The intensive efforts undertaken to develop an economically competitive SST are discussed. New design approaches in the areas of airpiene longitudinal control and stability and flight control systems design were developed. Extensive research work was

conducted to push the state of the art as hard as possible in the development of handling qualities criteria and in the design evolution of the stebility augmentation system. The end product was a control-configured vehicle employing multiple redundant electronic stability augmentation systems to meet design requirements for both normal handling qualities and minimum-safe handling qualities. This design approach contributed substantial gains in range/payload capability over that attainable through the conventional approach that inhibits airplane design through the requirement to provide inherent aerodynamic stability. Throughout all of the design development work the effects of structural aeroelastics on aircraft stability and control played a major role in configuration design decisions. The complex engineering work involved in the sercelastic analyses paced the configuration development design cycles and contributed substantially to the total engineering costs. The experience gained in these areas has identified the need for improved quality. automated aeroelastic analysis methods to speed the design development work and reduce the engineering costs and design

SYSTEM ANALYSIS FOR A BATTLE-FIELD AIR SUPERIOR-ITY FIGHTER PROJECT WITH RESPECT TO MINIMUM COST

Johannes Spintzyk In AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun 1974 14 p. refs (For availability see N74-31458 21-02)

The battle-field air superiority fighter is an air defense aircraft with the function to gain and to hold air superiority over the combat area for limited time and limited operational area. For given budget the fleet effectiveness can be optimized by reducing the price of the aircraft thus allowing for a higher number of aircraft. Mainly a low cost design can be achieved by minimizing the take-off weight. Design philosophy is to adjust range. payload and equipment to absolute necessary requirements thus arriving to a simple design, but not to compromise air combat capability. For the evaluation of different solutions a method is discussed which shows the role of aircraft characteristics with respect to air combat and which can be used in the preliminary design phases. In the present paper, the influence of mission and design parameters of range, combat time, wing loading and thrust/weight ratio on take-off weight, system cost and air combat. effectiveness for the battle-field air superiority fighter is shown. Different versions of a battle-field air superiority fighter are presented and comparative results shown.

POTENTIAL PAYOFF OF NEW ARRODYNAMIC PREDIC-TION METHODS

Richard H. Klepinger and Robert Weissman In AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 refs (For availability see N74-31458 21-02)

The trade studies and design compromises to optimize the aircraft configuration for specific purposes are discussed. Typical problems involved in the stroraft design process are examined. Illustrations are provided to show the performance improvement which resulted from design modifications to various aircraft. Methods for accurately prodicting the performance of an aircraft prior to flight test are reported. Design criteria based on lateral-directional static stability have been developed to reveal possible problems relative to departure characteristics and spin susceptibility. It is stated that the application of three dimensional

serodynamic analysis methods and spin prevention criteria early in the development of a new aircraft may be the key to better design optimization and improved integration of the compo-

DESIGN OPTIMIZATION OF THE VAK 1918 AND ITS EVALUATION BASED ON RESULTS FROM THE HARD-WARE REALISATION AND TEST DATA

Rolf Riccius and Bernhard Wolf In AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 19 p. refs (For availability sam N74-31456 21-02)

The design optimization procedure for the VAK 1918 fighter aircraft is discussed. The procedure of design optimization is evaluated based on the results obtained from ground and flight tests. The emphasis in the original planning was placed on sircraft performance. The results of the tradeoff studies in combination with point design studies are reported. The different approaches to the power plant selection are defined. The rationale behind the final selection of the serodynamic configuration is explained. Author

CONCEPT CCV AND SPECIFICATIONS

Jean-Claude Wanner /n AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 6 p. In FRENCH; ENGLISH summary (For availability see: N74-31458 21-02)

The application of the control configured vahicle (CCV) concept to the design stage of new aircraft is discussed. The systems considered under the CCV concept are (1) static stability compensation, (2) maneuver load control. (3) active ride control. and (4) active flutter control. The overall goal of the CCV concept is to take advantage of the most recent technological progress in electronics and to make use of new types of control actuators in order to satisfy the compromise between performance, handling qualities, lifetime, and cost.

N74-31481 Bosing Co., Wichita, Kans. INTRODUCTION OF CCV TECHNOLOGY INTO AIRPLANE DESIGN

Richard B. Holloway In AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 16 p refs (For availability see N74-31458 21-02)

The control configured vehicle (CCV) aircraft design process is compared with conventional design procedures. The CCV procedure capitalizes on the potential of considering advanced flight control concepts during the initial parametric studies and trades. Formulation of the parametric aircraft can also be altered by the CCV approach, since traditional empirical design procedures no longer necessarily apply. CCV studies indicate that the most significant performance improvements are achieved in the following functions. (1) augmented stability. (2) gust load alleviation, (3) maneuver load control. (4) fatigue reduction, (5) ride control, and (5) flutter mode control.

ADVANCEMENTS IN FUTURE FIGHTER AIRCRAFT
Wolfgang Herbst In AGARD Aircraft Design Integration and
Optimization, Vol. 1 Jun. 1974 7 p. refs (For availability see N74-31458 21-02)

An analysis of advanced design technology as applied to future lighter aircraft was conducted. The following conclusions were reached: (1) a new aircraft development can be justified if the performance of the new aircraft exceeds that of the old by 15 to 20 percent, (2) foresseable technological air frame advances. such as CCV and composites, do not justify the development of new weapon systems, per se, (3) refent engine technology advances allows a performance improvement which will justify new aircraft design, and (4) foreseeable air frame advances will pay off if applied to new aircraft development.

N74-31484 Ministry of Defence, London (England). ESTIMATION OF PROGRAMMES AND COSTS FOR MILITARY AIRCRAFT

J. C. Morrell In AGARD Aircraft Design Integration and Optimization, Vol. 1 Jun. 1974 14 p (For svalidability see N74-31458 21-02)

The purposes, history and methods of budgetery estimation for military alreaft development programs conducted by the United Kingdom are discussed. The derivation of the methods are analyzed using the airframe as the main example. The use of the timescale, resources, and cost estimating techniques to provide cost trade-offs for different siroraft operational capabilities is demonstrated. The main purposes served by the budgetary estimate. are. (1) planning and funding, (2) project selection, appraisal, and approval, and (3) assessment of future loading on the aircraft industry for serospace policy decisions.

PRELIMINARY AIRCRAFT DESIGN

Clem C. Weitsman Jun. 1974 189 p refs. Partly in ENGLISH and partly in FRENCH. Lecture series presented at Brunswick, West Germany, 6-7 May 1974, Breds, Netherlands, 9-10 May 1974, and Cranfield, England, 13-14 May 1974 (AGARD-LS-68) Avail: NTIS HC \$12.50

An analysis of preliminary aircraft design procedures was conducted to show the response to a proposed military requirement with the first estimate of a complete aircraft configuration. The decision rationals and the initial estimation of size, weights, lift and drag, performance, and cost is presented with respect to the payload for various eigenst types and classes and the proposed mission. Emphasis is placed on how this small preliminary design team must make the first decisions regarding technical feasibility and operational desirability. An experienced design team can predict with sufficient accuracy the overall weight. configuration, performance, and cost to permit confident decision to proceed with advanced development of the project. For Individual titles, see N74-32421 through N74-32426.

The satisfaction of military sirgraft requirements as it affects the size and performance of sirgraft is discussed. The basic boundaries for the new sirgraft design are defined as: (1) the operational concept for the dominating mission and physical boundaries, (2) the aircraft performance desired with respect to aircraft speed, range, altitude ceiling, acceleration, and payloads, and (3) physical constraints as determined by ground support facilities. The procedures to be followed in arriving at a three view drawing and a weight and balance statement are briefly explained. Some of the compromises which must be met in eircraft design are explained.

PRELIMINARY DESIGN OF CIVIL AND MILITARY AIR-CRAFT AT AVIONS MARCEL DASSAULT-BREQUET AVIATION

J. Czinczenheim In AGARD Prelim. Aircraft Design Jun. 1974 In FRENCH and ENGLISH (For availability see refs N74-32420 22-02)

The procedures followed by a French streraft manufacturing company in the design and production of military and civilian aircraft are discussed. The subjects considered include the following: (1) the organization of the preliminary project staff. (2) the responsibilities of the project engineer or program manager, and (3) iterative steps to be followed in arriving at the preliminary singraft configuration. The design procedures which followed in the development of specific military and civilian aircraft are analyzed. The steps which are taken to predict the performance of the preliminary design configuration are explained. The evaluation of lift and drag characteristics at the preliminary design stage is emphasized. The functions of a weapon system department with respect to the preliminary project phase, the detailed definition phase, integration tests, and the integration of production equipment are outlined.

W. W. Huff, Jr. In AGARD Freilm. Aircraft Design Jun. 1974 16 p refe (For availability see N74-32420 22-02)

The impact of computer technology on modern engineering methods for the preliminary design of aircraft is discussed. Large capacity digital computer systems and their peripheral equipments provide the opportunity to bring all significant technical and managerial disciplines together in an integrated program. Most

design synthesis computer programs are constructed in a modular fashion, which are controlled by the technical disciplines responsible for the state-of-the-art in each particular area. In general, these disciplines will apply the input data at a level of detail consistent with the phase of the preliminary design process. The phases of preliminary design which are considered are: (1) program definition, (2) concept formulation, and (3) contract definition.

(NASA CR-140939, AGARD-R 624) Avail NTIS HC \$3.75 CSCL 01C

Flight tests were performed on an F.5A arcraft to investing atte the dynamic buffet pressure distribution on the wing surfaces and the responses during a series of transonic maneuvers called wind up turns. The conditions under which the tests were conducted are defined. The fluctuating buffet pressure data on the right wing of the sincraft were acquired by ministurized semiconductor-type pressure transducers flush mounted on the wing. Processing of the fluctuating pressures and responses included the generation of the auto- and cross-power spectra, and of the spatial correlation functions. An analytical correlation procedure was introduced to compute the shoraft response spectra based on the measured buffet pressures.

USE OF RADIOSONDE DATA TO DERIVE ATMOSPHERIC WIND SHEARS FOR SMALL SHEAR INCREMENTS

Oskar M. Essenwanger /n AGARD Effects of Surface Winds and Gusts on Aircraft Design and Operation Nov. 1974 p 79-88 refs (For availability see N75-15841 07-05)

The wind vector shear in the lowest 5000 feet for the 90, 95 and 99 percent threshold of the annual ournulative distribution and the maximum shear from 14 stations of the olimatological ringbook and 27 stations of unpublished vector shear distributions are derived. All data were normalized to a 100 m shear interval by a formula. The outcome of the analysis confirms that the vector shear decreases from the surface to a minimum at around 2 km. A definite latitudinal dependence can be discovered with the mid-latitudes exposing the strongest shear while the polar or tropical zones display significantly lower values. Tables for 100 m and 50 m shear intervals are given for the average 90, 95 and 99 percent threshold and the maximum shear within three typical geographic zones (polar, mid-latitude and tropical), and for the station with the strongest shears within that zone.

FLUTTER SUPPRESSION AND STRUCTURAL LOAD ALLEVIATION

Jul. 1975 94 p. refs. in ENGLISH and partly in FRENCH Presented at the 40th meeting of the Struct; and Mater. Panel, Brussele, 13-18 Apr. 1975 (AGARD-CP-175) Avail: NTIS HC \$4.75

Conference data on advances made in the eres of flutter suppression and structrual load alleviation are summarized. Particular attention was given to system design, behavior, reliability, safety and redundancy, as found by analyses, model and flight tests. The use of active controls to suppress flutter was the dominant subject. The general problem was explored and specific examples and experiences were also presented. Flutter control of the wing/store combination, of the empannage and of a straight wing were studied, wind tunnel tests were discussed, automatic pilotage in turbulent air was examined and the mechanization of active controls was reviewed. For individual titles, see N75-32097 through N75-32104.

N75-32097 McDonnell Altereft Co., St. Louis, Mo. DESIGN CONSIDERATIONS FOR AN ACTIVE SUPPRESSION SYSTEM FOR FIGHTER WING/STORE FLUTTER C. H. Perisho, W. E. Triplett, and W. J. Mykytow (AFFDL) In AGARD Flutter Suppression and Structural Load Alleviation Jul. 1975 19 p. refs (For availability see N75-32095 23-05)

Results from a previous study on wing/store flutter are extended in a preliminary system design to determine realistic system integration features, and to provide a fassibility evaluation of a completely automatic, pilot-out-of-the-loop, adaptive active flutter control system which automatically adjusts a system gain and compensation for different stores on the alcuraft. Information obtained included a definition of details involving hydraulic and structural modifications, hardwere and software components, flight safety features, expected performance benefits and limitations, and program plans for a wind tunnel verification effort and subsequent flight test demonstrations.

ACTIVE FLUTTER SUPPRESSION

M. R. Turner In AGARD Flutter Suppression and Structural Load Alleviation Jul. 1975 14 p refs (For availability see N75-32095 23-05)

The use of Root-locus, Nyquist plots and state space theory in the design of active flutter suppression feedback laws is discussed. The concept of an optimum flutter suppression pole placement requirement is introduced. Osscription and examples are given of Dressler's and Kalman's dynamic observers for state space feedback when only one transducer is used. Examples are given of the effectivelises of freabsok laws at off-design conditions for three different types of streats. The effect of sileron power control unit rate limit on the sileron control of haud flutter of a high aspect ratio wing in the presence of discrets and random gusts was shown. For a capability of 180 deg/sec., a 20 percent increase of flutter speed can be softward with very large weight savings. The cutoff frequency usually quoted for the transfer function of power control units is shown to underestimate its flutter control capabilities. The possible need for feedback laws based upon flight test measurements is

ACTIVE CONTROL OF EMPENNAGE FLUTTER

O. Sensburg, H. Hoenlinger, and M. Kuehn. In AGARD. Flutter Suppression and Structural Loed Alleviation. Jul. 1975. 11 p. refs (For availability see N75-32096 23-05)

After a successful application of the active flutter control technology on a wingstore flutter problem, an extension of this technology to an empennage fluster problem was considered. The task was to develop, build and test a control system which actively suppresses a total airplane model flutter problem by counteracting with a hydraulically driven rudder. The flutter phenomenon described is characterized by large contributions of fuselage torsional movement therefore producing high inertial forces in comparison with unsteady serodynamic forces. These properties lead to a mild onset of flutter. For the same reason no rapid phase changes of the flutter mode near the flutter point are necurring

N76-32100 Boeing Co., Wichita, Kens. WIND TUNNEL INVESTIGATION OF CONTROL CONFIG-URED VEHICLE SYSTEMS

G. O. Thompson and F. D. Sevart In AGARD Flutter Suppression and Structural Load Alleviation Jul. 1975 8 p

availability see N75-32096 23-05)

Research studies was conducted to demonstrate active flutter mode control and forward body ride control systems on a one-thirtieth scale 8-526 seroelastic model. The NASA model, originally designed and constructed for low speed gust response testing, was modified to represent the simplane used in the 8-52 control configured vehicle (CCV) fight test program. The CCV program flutter mode control and vertical ride control systems were scaled to model frequency and tested in the transcolo dynamics tunnel at conditions equivalent to sirplene flight test conditions. Wind tunnel test results were compared with model analytical and airplane flight test results. The good correlation demonstrates wind tunnel test models can be employed to verify CCV system analysis and synthesis results, thus reducing risks involved in a new simplene development.

N75-32101 Office National d'Etudes et de Recherches Asconnatiales, Paris (France) CLOSED FORM EXPRESSION OF THE OPTIMAL CONTROL

OF A RIGID AIRPLANE TO TURBULENCE Gabriel Coupry In AGARD Flutter Suppression and Structural Load Alleviation Jul. 1975 B p. refs. in FRENCH; ENGLISH summary (For availability see: N75-32096 23-05)

An explanation is given as to how Wiener's theory makes it possible to derive in closed form, the transfer function of the filter used for control. It shows that this transfer function can be expressed in autoadaptative form, the poles being proportional to the velocity of the aircraft. The influence of parameters like mass, scale of turbulence, is discussed. Finally, a comparison is given between results of flight test and prediction. Author

N75-32102 Office National d'Etudes et de Recherches Aerospatiales, Paris (France). WIND TUNNEL TEST OF A FLUTTER SUPPRESSOR ON A STRAIGHT WING

Roger Destuynder in AGARD Flutter Suppression and Structural Load Alleviation Jul. 1978 3 p. In FRENCH; ENGLISH summary

(For availability see N75-32096 23-05)

A study was made of flutter due to a load hung under the wing of an aircraft. Special attention was given to aerodynamic and natural structural modes. Using an aerodynamically undoubled control surface made it possible to simplify the transfer function of the servo-system. The control obtained this way is not optimal, but it does not require a precise knowledge of the serodynamic forces and the wing dynamic characteristics, and provides an increased damping ratio in the whole velocity range. Author

HANDLING QUALITIES SPECIFICATION DEFICIENCIES

A. G. Barnes Nov. 1975 23 p. refs
(AGARD-AR-89). Avail: NTIS. HC \$3.60

A summary is presented on the contributions received from NATO nations on the deficiencies of six different handling qualities specifications. They are: Mil-H-8501, Mil-F-8786-B. TSS-3. Mil-F-83300, AR 577, AvP 970. The purpose was to determine those portions of the various handling qualities specifications which were inadequate or overly restrictive. The result shows that there were not a great many nevere deficiencies, and those that were found were not entirely unexpected. The collected comments illustrate the difficulty of collecting information from design or certification authorities which quantifies flying qualities. Difficulties arise because the information needed to compare an early aircraft design with a current specification is often not svallable; also there is a reluctance to publicize information which might show a particular aircraft in a bad light. The need for further research is shown.

EVOLUTION OF THE ROLE PLAYED BY THE STREET ANALYSIS OFFICE IN THE DESIGN OF A PROTOTYPE (EVOLUTION DU ROLE DU BUREAU DES STRUCTURES DANS LA REALISATION D'UN PROTOTYPE

Marcel Payrony In AGARD Specialists Meeting on Structural Design Technology Nov 1975 8 p in FRENCH (For availability see N76-17092 08-05)

Changes that have taken place in the work organization of the stress analysis and aircraft structures design office during the last few years due to the introduction of computer techniques were reviewed. The relative advantages and disadvantages of plotters and interactive graphics terminals were summerized. A number of computer programs used in the design of representative stroraft structures and elements were mentioned. Problems related to computer running time and the inputting and retrieval of data into and from computers were described. Applications to the Mercure and Falcon 50 aircraft were mentioned and Transi. by Y.J.A.

N76-17095 Westland Helicopters, Ltd., Yeovil (England). THE STRUCTURAL DESIGN PROCESS FOR HELICOPTERS WITH EMPHASIS ON THE NOTOR

D. A. S. Howell In AGARD Specialists Meeting on Structural Design Technology Nov. 1975 18 p ref (For availability see N76-17092 08-05)

The heliconter structural designer must develop an awareness of many potential design problems not encountered in the fixed wing field. The solution of these problems invariably involves the three disciplines of dynamics, serodynamics and stress, and is further complicated by the increasingly stringent demands of the overall performance requirements. These particular aspects of helicopter design as well as the design process are introduced by the paper, which also considers the role of the structural designer during the development phase of the helicopter. The development of new enalytical and experimental techniques, the application of new materials, and some structural design objectives are also presented with a view to enhancing further the capabilities

N76-17096 Technische Hogeschool, Delft (Netherlands) THE PROBLEMS ASSOCIATED WITH INTERNATIONAL DESIGN TEAMS AND THEIR SOLUTIONS

E. J. VanBeak In AGARD Specialists Meeting on Structural Design Technology Nov. 1975 4 p (For availability see N76-17092 08-051

Some problems relating to international cooperation in design of sircraft and possible solutions for these problems are discussed The strong identity of experienced design organizations, based on tradition and a long islatory, initially results in many difficulties and differences of opinion, before a smoothly running cooperation has been achieved. Other important factors are variations in the drawing numbering systems, affecting the modification system used during the design phase and thereafter. There are the problems related to normalization and standardization of standard parts, and there is still a large variation in national material specifications for basically the same material. Variations in the national airworthiness requirements resulting in special conditions are an important feature in multi-national design cooperation.

Busides a discussion of the state of the art concerning materials, a summary is presented about work with now materials at AERITALIA and Messershmitt-Boelkow-Biohm. Special attention is given to materials for lighter aircraft structures

N76-17098 General Dynamics/Fort Worth, Tex THE ROLES OF ANALYSIS IN RELATION TO STRUCTURAL TESTING

William C. Dietz and Lawrence C. Seth In AGARD Specialists Meeting on Structural Design Technology Nov 1975 14 p

(For availability see N76-17092 06-05)

The relationship between analysis and test is explained for a typical modern fighter altoraft. The role each plays as a part of the total structural certification program is emphasized for each element of the structural design process. These include the efforts involved in development of basic allowable stresses for design, wind tunnel testing, loads and stress analysis, full scale tost, and flight test. Currently used methods and procedures for solution of recent problems in schieving economically durable sinframe structure and the approach to the application of composites are reviewed Author

THE USE OF COMPUTERS TO DEFINE MILITARY AIN-CRAFT STHUCTURES

I. C. Taig In AGARD Specialists Meeting on Structural Design Technology Nov. 1975 32 p refs (For availability see N76-17092

The use of the computer as a tool to aid structural design has become firmly established during the last twenty years. In particular, it is probably true that in no other area of computer operation has greater progress been made than in structural analysis. The present state of the art in the related use of computers is surveyed and benefits and panalties which result therefrom are discussed. Author

N76-17100 McDonnell Aircraft Co., St. Louis, Mo WEIGHT CONTROL AND THE INFLUENCE OF MANUFAC-TURING ON STRUCTURAL DESIGN

R. C. Goran In AGARD Specialists Meeting on Structural Nov 1975 16 p (For availability see Derign Technology N76-17092 08-05)

Practices of weight control and the influence of manufacturing on structural design are discussed for the F-4 series of arroraft. the F-15 air superiority aircraft, and the DC-10 wing for commercial aircraft Many of the problems are a result of the constant need to design efficient lighter weight structures by the introduction of new materials, configurations, and joining methods, together with closer tolerances. To some extent, optimum design and minimum manufacturing cost appear divergent in nature. Much of the interaction between design and manufacturing is to comprornise or seek acceptance for seemingly conflicting requirements.

N76-18108# Advisory Group for Anrospace Research and Development, Paris (France) CURRENT STANDARDS OF FATIGUE TEST ON STRIKE AIRCRAFT

R. D. J. Maxwell (RAE, Farnborough, Engl.) Jan 1976 13 p (AGARD-AR-92: ISBN 92-836-1206-7)

HC \$3.50

The major fatigue test constitutes one of the most important aspects in almost all modern (actical aircraft designs. Within NATO, where numerous different tectical siteraft are employed. and where several user nations may operate an aircraft built by a different nation, it is important that the major fatigue test be performed in such a manner that the results can be interpreted and used by the various countries concerned. This Advisory Report, therefore, presents a statement of the objectives of a fatigue test, a list of uscential steps needed to achieve the objectives. a summary of recommendations of the way the steps should be carried out and a review of the background philosophy behind the recommendations.

MISSION SPECTRA FOR THE COMPUTATION OF LIFE Expectancies [Spectres de Mission pour le CALCUL DES DURGES DE VIE

Liard In its Helicopter Design Mission Load Spectra 1976 10 p in FRENCH (For availability see N76-30207 21-05)

The computation of the life expectancies for helicopter parts was shown to be strongly affected by the assumptions made in the type of missions to be performed it appears preferable to restrict oneself to the most important flight characteristics, such as speed and load factor, instead of including more elaborate data (such as constraints) which cannot be carried over to the design of new helicopters. The choice of helicopters selected should be based on a statistical sampling of the air fleet considered to give reliable information on the average mission spectra of these helicopters, rather than to focus the attention on the single helicopter with the most severe utilization; the reason for this is that it is extremely unlikely that the weakest part would be found on the most highly stressed machine. THE IMPACT OF HELICOPTER MISSION SPECTRA ON PATIGUE

G. Reichert In AGARD Helicopter Design Mission Load Spectra Aug. 1976 17 p. refs (For evallability see N76-30207 21-05)

Helicopter components are requested to have long service lives, coming close to unlimited lifetimes. However, there are still real problems in the accurate prediction of the resulting component lives because this requires the availability of adequate mission load spectra. The nature of the typical fatigue loading situation, in combination with the requested long lifetimes raises the question of the sensitivity to variations in mission requirements and load spectra. For a light inelicopter with a hingeless rotor system using fiberglass rotor blades in commercial as well as in military application - the influence of different mission requirements on load spectra and fatigue is discussed Normally, only a small portion of the complete mission is of importance for fatigue. Therefore, the impact of modified mission spectra on fatigue is assessed.

HELICOPTER DESIGN MISSION LOAD SPECTRA
A. D. Hall In AGARD Helicopter Design Mission Load Spectra
Aug. 1976 5 p (For availability see N78-30207 21-05)

The various stages of heilcopter design are related to projected flight mission fatigue load magnitudes and occurrences. The latter were expressed as a percentage of total flying time or as a number of occurrences per hour of flight. Magnitude of loading was derived for the design stage from calculation or by parametric readout from similar aircraft types. The assumed maneuver spectrum was the critical link in developing the design stage, throughout prototype development and model fatigue teating.

US AIR FORCE HELICOPTER OPERATIONAL FLIGHT SPECTRA SURVEY PROGRAM: FAST AND PRESENT G. L. Maitin and R. B. Johnson, Jr. In AGARD Helicopter Design Mission Load Spectrum. Aug. 1978—16 p. refs. (For availability see N76-30207 21-05)

Davelopment and application of the Flight Condition Recognition (FCR) technique for the processing of helicopter operational data are elaborated. The FCR technique Identifies aircraft operations and transitions which are called flight conditions, and flight phases which are called mission segments. Each identification is based on the characteristic behavior of the in-flight parameters. With such identifications, the data processing consists basically of determining the occurrences and durations of the flight conditions and mission segments, of measuring the in-flight parameters, and accordingly of presenting these data so that the flight condition and mission segment time and frequency distributions are quantitatively defined by selected ranges of the flight parameters. This application of the FCR technique permits the fatigue analyst to comprehend and apply more effectively the operational usage spectrum to the calculation of the fatigue life of critical helicopter components.

N76-32184 Bosing Co., Seattle, Wash ADVANCES IN ENGINE BURST CONTAINMENT

R J Bristow, C. D Davidson, and J H Gerstle In AGARD Advan in Eng. Burst Containment and Finite Elem Appl. to Battle Damaged Struct. Sep. 1978 p. 1.6 (For availability see N76-32183-23-05)

A partial review of recent research performed into the application of fragment impact studies leading to an understanding of engine burst fragment impacts and the initial development of an engine burst containment system using duPont Kevlar material were described. All test work to dete has involved translational accelerators. The program has not yet resulted in a satisfactory containment system, in addition 17 a summary of program accomplishments, several areas where unexpected results occurred and where information was obtained that may influence future fragment containment efforts were discussed. One of these areas involves spinning fragments. None of the predicted adverse effects in Kevlar fabric was found. Another area concerns thermal effects, it was found that the efficiency of the barrier in stopping fragments was influenced by the temperature of the Kevlar.

Examples of non-linear vibration behavior in ground resonance tests of an aircraft are shown. Model tests for a simplified system with non-linear properties have been performed, to study the offects of friction and backlash with respect to ground resonance test and flight flutter test. With symmetric and asymmetric non-linear stiffness characteristics effects of amplitude dependent frequencies, mode coupling, mode asymmetries and the consequences in parameter identification in vibration tests are politied out and discussed. In case of flutter critical modes the problems of apparent damping caused by non-linear system properties are shown, and recommendations are given to reach a representative flutter clearance with respect to this non-linear system behavior.

AVIONICE COOLING ON USAF AIRCRAFT

George C. Letton, Jr. In AGARD Avionic Cooling and Power Supplies for Advanced Altroaft Nov. 1978 9 p refs (Foi primary document see N77-18031 07-05)

AVMI: NTIS HC A11/MF A01

There is a continual effort by the United States Air Force to provide improved avionics equipment on today's USAF aircraft were reviewed and approaches which will improve avionics reliability, reduce aircraft penalty and lower life cycle cost, were outlined. Greater emphasis is needed on producing compatible avionics equipment and cooling systems. A comprehensive trade study of avionics reliability versus environmental control system (ECS) cooling capability should be conducted at the start of the aircraft development program. From this trade study, the ECS cooling capability can be optimized to minimize total aircraft life cycle cost. The avionics contractor should conduct a detailed analytical thermal analysis of internal black box temperatures early in the development program. During qualification testing. a thermal verification test should be conducted to verify that all component temperatures are within the necessary limits for required reliability. Use of narrow limits on inlet coolant te.nperature, greater use of cold plates and liquid cooling, and use of ECS approaches similar to the Advanced Environmental Control System should be seriously considered for new aircraft

NOTICE. Available to U.S. Government Agencies.

The operational concept is one of complementing tactical air forces by employing unmanned aircraft (UMA) to carry out conventional attacks against vital counter-air targets. A UMA modular design configuration was used which permits essy conversion to alternate missions and provides a step by step advancement from an attack drone to an attack remoted piloted vehicle and finally to the more sophisticated autonomous terminal attack drone. The UMA system capabilities were analyzed quantitatively by considering the subsytems, the total system, cost, weapons, delivery, survivability/vulnerability, and life cycle cost. Major technology areas requiring additional efforts in order to achieve the capability to perform the postulated missions effectively were identified.

AGARD FLIGHT TEST INSTRUMENTATION SERIES.
VOLUME 5: MAGNETIC RECORDING OF FLIGHT TEST

G. E. Bennett, W. D. Mace, ed., and A. Pool, ed. Feb. 1974.

(AGARDograph-160-Vol-5; AGARD-AG-180-Vol-5) Avail: NTIS HC \$7.00

An assessment of the general requirement for a flight test data acquisition system is followed with a general discussion of the complete system. The more important individual functions of the system are those most intimately involved in determining the performance of the system and its efficiency in acquiring the data. In the case of the recording aspects emphasis is placed on the basic recording process, its capabilities and its problems, and on the techniques necessary to overcome its shortcomings. Basic design principles of airborne tape transports and the characteristics of write/read heads and magnetic tape are as discussed.

AGARD FLIGHT TEST INSTRUMENTATION SERVICES.
VOLUME 1: BASIC PRINCIPLES OF FLIGHT TEST
INSTRUMENTATION ENGINEERING

A. Pool, ed. and D. Bosman, ed. Apr. 1974 168 p. refs (AGARDograph-180-Vol-1; AGARD-AG-160-Vol-1) Avail. NTIS HC \$11.50

Monographs on the more important aspects of flight test instrumentation are presented. The subjects discussed include: (1) in-flight temperature measurements, (2) fuel flow and engine rotation speed measurements, (3) open and disced-loop accelerometers, and (4) magnetic tape recording. The main emphasis is an large automated instrumentation systems for the initial flight testing of modern military and civil alroraft. The overall areas of consideration are the design of the instrumentation system, the characteristics of the individual measuring channel, and the integration of the individual data channels into one data collection system. For individual titles, see N74-25934 through N74-25945.

THE USERS' REQUIREMENTS

M. L. Henney In AGARD AGARD Flight Test Instrumentation Ser., Vol. 1 Apr. 1974 9 p refs (For availability see N74-25933 15-14)

The process for determining the general requirements for a flight test instrumentation system is discussed. The menner in which the requirements are derived is indicated by considering the test planning process and data analysis. Specific requirements arising in various categories of tests are detailed. Explanation of the data analysis requirements is given. The application of the selection process to flight tests of uncertificated and certificated alreaft is compared.

AGARD FLIGHT TEST INSTRUMENTATION SERIES. VOLUME 6: OPEN AND CLOSED LOOP ACCELEROME-

I. MoLaren (RAE), W. D. Mace, ed., and A. Pool, ed. Jul. 1974 46 p refs (AGARD-AG-160-Vol-6; AGARDograph-160-Vol-6) Avail: NTIS

HC \$5.50

The state-of-the-art of both open and closed loop accelerometers used for sircreft flight test work, covering system and component analysis and basic hardware design is discussed. Both physical design problems and mathematical analysis are covered and special emphasis is put on those aspects likely to be relevant to aircraft flight test work. Performance details include repeatabliity, compensation for temperature variation, insusceptibility to cross effects, stability under vibration and frequency response.

The application of accelerometers in several flight test techniques together with their performance requirements are reviewed in order to guide the flight test engineer in making his choice of instrument in any particular case. The principles of frequency response tests are discussed in association with the theoretical characteristics of various, nominally, second order systems which are modified either by the method of testing or by the inherent, practical difficulties of instrument design. ELECTRONIC AIRBORNE DISPLAYS

Dec. 1975 430 p refs in ENGLISH and FRENCH Presented at the Avionics Panel Symp., Edinburgh, 7-11 Apr. 1975 (AGARD-CP-167) Avail: NTIS HC \$11.75

Problems of airborne displays were considered. Reports in the following areas were presented: trends in the field of airborne displays, evaluation and assessment procedures for airborne display systems, display devices and materials, data processing, and displays for particular applications. For individual titles, see N76-17108 through N76-17140.

N76-17108 Thomson-CSF, Malakoff (France). Equipements Avioniques THE IMPACT OF MODERN ELECTRONIC AIRBORNE DISPLAYS IN FUTURE AVIATION

Y. Brault In AGARD Electron. Airborne Displays Dec. 1975 8 p in FRENCH (For availability see N76-17107 US-06)

The expected impact of modern electronic airborne display systems on future singraft was presented, with emphasis on the need to improve man-machine interactions, especially in military aviation. The need is imposed by the following fantors: (1) the setting of more and more complex operational flying missions, (2) the introduction of alreraft (interceptors, fixed and rotating wing attack models) with ever higher performance. (3) the introduction of more and more diversified weapon systems, (4) the existence of an extremely lethal and complex environment. Future applications to civil aviation were also briefly mentioned. PERFORMANCE REQUIREMENTS FOR AIRBORNE MUL-TIFUNCTION DISPLAY SYSTEMS

G. Mann In AGARD Electron. Airborne Displays Dec. 1975 6 p. refs (For availability see N75-17107 08-06)

Any airborne multifunction display must by definition be capable of presenting information from a variety of sensors and data sources. Some of these sensors and their critical parameters are briefly considered in relation to their display requirments. The multifunction display may need to be compatible with any such sensor or source and also with computer generated symbology derived from instrumentation sensors and weapon systems. The input sources which appear to require the highest performance from airborne displays are those of the current and future image forming sensors. There is a danger that many systems using multifunction displays could be display limited unless the complex interaction between sensor, display and observer is understood. Author

COMPARISON OF CONVENTIONAL AND ADVANCED AIRCRAFT DISPLAYS

Raif Beyer (Techn. Univ., Brunswick) In AGARD Electron. Airborne Displays Dec. 1975 7 p. refs (For availability see N76-17107 OR-06)

The comparison of conventional and advanced sircraft displays often requires a discrimination of two sample means of pilotis performance and workload measures for a limited sample size, a postulated minimum difference of means and a given error probability. Under these conditions significant results may be obtained only if the population variance does not exceed a certain limit Some major sources of variability and their influence on the significance of experimental results are discussed. Furthermore two different philosophies of evaluation of displays are presented as well as some experiences with pilot's performance and workload measures employed in flight sharehold inflight investigations of displays.

COLOR AND BRIGHTNESS REQUIREMENTS FOR COCKPIT DISPLAYS PROPOSAL TO EVALUATE THEIR CHARACTER-ISTICS

J. P. Galves and J. Brun In AGARD Electron. Airborne Displays Dec. 1975 8 p. ref. In FRENCH; ENGLISH summary (For availability see N76-17107 08-06)

introduction of color coding for information displays added several qualities to the already existing monochromatic electronic aircraft display. The information density to be displayed is increased, and the data acquisition time and the error possibilities are reduced. These advantages are fundamental in order to display graphic and numerical informations and lighted areas for jet plane flights control (map display, hud). These informations have to be detected by the pilot for every surround illumination level. An experimental work schedule, associating brightness and chrominance measurements on one hand, and visual perception of operators on the other, permitted to separate different parameters and to formulate several definitions about brightness and color contrast, the interaction between these two parameters and their measuring conditions. 'Detection Index' and 'Discrimination Index' notions are introduced. These parameters can be measured and permit to easyly evaluate the display quality for every background and surround illumination Minimum index values are proposed for a confortable detection and identification of standard symbols especially in the case of direct sunlight on the displaying poard. Color display used is a color CRT with a penetration screen developed by THOMSON-CSF for 'Head down' and 'Head up' display. Definition and standard introduced can be applied to every color or monochromatic display such as plasma panel, liquid crystals, LED or any electromechanical

N76-17114 Ferranti, Ltd., Edinburgh (Scotland). INTEGRATED MULTI-FUNCTION COCKPIT DISPLAY SYSTEMS

J. M. Braid In AGARD Electron, Airborne Displays Dec. 1975 13 p. refs (For availability see: N76-17107-08-06)

The multifunction display concept and the necessity for its efficient integration to most the more demanding future tasks are defined briefly. Attention is drawn to the potential shortcomings of past arrangements, particularly in the pilot's cockpit. The different data sources and sensors, categories of airborne display, display devices and types of drive signals are described and reference is made to their compatibility. Particular mention is made of cursive, raster and cursive-on-raster writing. An example is given of how the various elements in the system can be integrated with integrity, into a system which permits more

attention to be paid to the achievement of a satisfactory man-machine interface, without compromising individual sensor performance. Diagrams and photographs demonstrate the feasibility of the concept and compatibility of the hardware within the cockpit constraints. Pitfalls facing the implementation of such a system are included and the probable areas of conflict and reward are established.

N76-17116 Transportation Systems Center, Cambridge, Mass. AN EXPERIMENTAL EVALUATION OF VARIOUS ELECTRONIC COCKPIT DISPLAYS FOR AIR/GROUND DATA LINK COMMUNICATIONS

R. W. Wisteder, J. F. Cenniff, and E. H. Hilborn. In AGARD Electron. Airborne Displays. Dec. 1975. 34 p. refs (For availability see N76-17107 08-06)

A series of laboratory and cockpit simulator experiments was conducted by the Department of Transportation, Transportation Systems Center in a study of the human factors aspects of a cookpit digital data link system for air traffic control (ATC) and airline company business communications. The laboratory experiments utilized photographic slides to study message formatting. The simulator experiments evaluated visual displays, computer generated synthetic speech and pilot input devices The potential of data link for reducing pilot workload and channel congestion while providing efficient communications in a highly automated ATC system is of great interest to the Federal Aviation Administration. The experimental results to date led to the recommendation of a 16-character short message display, development of some guidelines for abbreviating and formatting messages, and the conclusion that pilots can effectively communloate using visual displays, synthetic speech, and pushbutton keysets, with an overall reduction in workload.

NEW ELECTRONIC DISPLAY SYSTEMS FOR AIRCRAFT INSTRUMENT PANELS [NOUVEAUX DISPOSITIFS DE VISUALISATION ELECTRONIQUE SUR PLANCHES DE BORD D'AVIONS]

M. Coussediere In AGARD Electron, Airboine Displays Dec. 1975 7 p. in FRENCH (For evallability see N76-17107 08-02)

Concepts for new electronic display systems for aircraft instrument panels were proposed, emphasizing the need to integrate and synthesize the information presently given by a number of different instruments. These new systems can either take the form of 'head-up' or 'head-down' display devices depending on the type and phase of each flight or mission. Such systems would present the following advantages: (1) presentation of more information in less space, (2) presentation of the information that is only required during a specific flight or mission situation, (3) greater flexibility and targe information carrying capacity, (4) presentation of the instantaneous position of the aircraft and prediction of its future flight path. The hardware used in the construction of these display systems could either be based on the present state of the art and include multicolored CRT's, or could include new techniques now under study such as plasmas or liquid crystals. Transi. by Y.J.A

N75-17118 Ferranti, Ltd., Oldham (Englandi, CRT'8 FOR ELECTRONIC AIRBORNE DISPLAYS M. R. Bennett /n AGARD Electron, Airborne Displays Dac 1975 13 p. refs (For svallability see N76-17107 08-06)

The two CRT display systems currently under development are described. The first is a packaged 178 x 127mm head down display (HDD) CRT. The design concept and subsequent selection of the various afternative parameters which were available at the start of the development are described. Each parameter is taken separately and the analysis and subsequent results are described. Full details are given of a final package design currently nearing completion which is intended to be fitted into a Hawker

Hunter aircraft of RAE Farnborough for flight trails to evaluate the performance under real direct sunlight and sunlit cloud conditions. The prime design consideration for this CRT was the combination of a suitable contrast enhancement technique together with the best currently available phosphor for operation at high brightness levels. The second CRT package described was again developed using a number of individual steps to optimize the design for a particular application. In this case the application was for a helmet mounted head up diaptay (HMHIID) CRT. Reduced weight and size were necessary in order to harmonize with the current helmet display concepts. This CRT was based on a commercial tube 028/9702Kh and the VX1778 designs which preceded it. The individual parameters are analyzed

N76-17119 Thomson-CSF, Paris (France). Groupement Tubes Electroniques

COLOR HEAD DOWN AND HEAD UP CRT'S FOR COCKPIT DISPLAYS

A. Martin and J. Brun In AGARD Election, Airborne Displays Dec. 1975 8 p. in FRENCH; ENGLISH summary (For availability see N76-17107 (8-06)

Important development work, during several years, led to the use of color CRT in crockpit displays. The characteristics of these tubes and their behavior in sirplanes are discussed. A separate program allowed the measurement of illumination range found during flight, for determining visibility conditions of instrument boards from complete darkness to sunlight illuminance. A simulator was built which reconstitutes the lighting conditions. Color display, incorporating color CRT, ellowing simultaneous presentation of symbols in several colors, luminance and shape were tested. Messurements of detection index, as described in another lecture, were carried on to evaluate conditions of perfectly confortable vision and conditions of 100% accuracy indication of color symbols displayed by color CRT. A 7 inch diagonal rectangular color CRT THX813-E17, meeting these specifications was developed for head down utilization. The tube incorporates a penetration screen displaying red at 10 kV, amber at 13 kV and green at 17 kV. The electron gun was designed to face beam intensity requirements at all colors and symbol luminances. An electrostatic focusing with zero current need, with focus voltage linearly dependent of screen voltage just requests single high voltage power supply for tube drive. The CRT is ruggedized and double heater gun has been adapted in order to increase reliability. Under sunlight illumination (7,000 fc), detection index over 1 were schieved, and detection index over 2 allowing very confortable vision were obtained in other less stringent conditions.

SOLID STATE FLIGHT INSTRUMENT DEVELOPMENT Wayne R. Clements In AGARD Electron. Airborne Displays Dec. 1975 4 p (For availability see N76-17107 08-06)

An Air Force Advanced Development Program is investigating the applicability of dot matrix displays for flight control instrumentation. Program goals include flat panel design, digital addressability, format flexibility and multi-function operability. Validation of the technology was reported and addressed the areas of technology selection and fabrication techniques, optical contrast enhancement filtering, and dot matrix standards for legibility and design. The light emitting diode (LED) technology was selected as it fulfilled program objectives and did not require a research breakthrough prior to application. Fabrication techniques were demonstrated and are within the realm of a high volume production method. Acceptable contrast enhancement via filtering resulted from the combination of a circular polarizer, band pass element, and antireflective coatings. A contrast ratio of 6:1 under the high ambient condition, i.e., 10,000 foot candles (fc), can be achieved. Human factors studies showed little, if any, performance differences between the display of punctate and continuous symbology

Royal Radar Establishment, Malvern (England). N76-17121

LIQUID CRYSTAL DISPLAY DEVICES

E. P. Raynes In AGARD Electron. Airborne Displays
1975 14 p. refs (For svallability see N78-17107-08-06)

Liquid crystals enable low voltage (approximately 3 volt) low power (approximately 1 micro-W) displays to be made which are readable in high ambient light level and can be as large as 30 cms by 30 cms. After a brief introduction to the liquid crystalline state, the busis and the operation are described of the twisted nematic effect, which has become the most widely used liquid crystal electro-optic effect. Basic device construction is also reviewed. The origin of patches of different contrast in these devices is discussed together with methods of eliminating them to produce devices with uniform contrast. Considerable progress has been made since the invention of the dyanobiphenyls in producing stable, coloriess, low viscosity liquid crystals usable over the temperature range of -10 to +60 C. This progress is reviewed. The problems encountered with the extended temperature range required for cockpit displays and the displaying of complex alpha-numeric information is examined.

N76-17122 Royal Redar Establishment, Malvern (Erigland). MULTICOLOUR DISPLAYS USING A LIQUID CRYSTAL COLOUR SWITCK

len A. Shanks In AGARD Electron, Airborne Displays 1975 11 p refs (For availability see N76-17107 08-06)

The conversion of a monochrome CRT display to a two color frame sequential display was demonstrated using a flat liquid crystal electro-optical color switch. The use of a similar device as a polarization switch permitted the production of a frame sequential stereoscopic CRT display which may be monochrome or color. Switching speeds of 1 maec at repatition rates up to 40 Hz are achieved by using an appropriate two frequency drive to the liquid crystal cell. This is sufficiently fast to meet frame sequential requirements. The construction, properties and performance of these devices are described and their advantages and limitations are discussed in relation to cockpit displays and other military applications.

N76-17123 Services Electronics Research Lab., Baldouk (England).

ELECTRONICALLY-CONTROLLED LIQUID-CRYSTAL GRA-TICULES FOR USE IN OPTICAL SYSTEMS

C. H. Gooch and R. C. Bottomley In AGARD Electron. Airborne Displays Dec. 1975 B p refs (For availability see N76-17107

In a number of optical systems there is a requirement for a graticule whose position in the field of view can be controlled electronically. This may be achieved by a liquid crystal device addressed by MOS circuits built onto the display. The device described gives a graticula display of 400 x 150 lines and achieves a resolution of 10 lines/mm.

N76-17124 Sperry Rand Corp., Phoenix, Ariz.
RECENT HARDWARE DEVELOPMENTS FOR ELECTRONIC DISPLAY SYSTEMS FOR US MILITARY AIRCRAFT Richard A. Wallace In AGARD Electron, Airborne Displays

Dec. 1975 12 p (For availability see N75-17107 08-06)
The hardware dasign tradeoffs required to meet the varied requirements of several CRT cookpit display systems are discussed. The multimode display systems use both strake and rester techniques to present varied formats of data from radar. TV, IR, attitude, fire nontrol, flight director, and other aircraft systems. These display requirements are translated into CRT, phosphor-filter, high voltage, video, deflection, and symbol generator requirements. Power and thermal considerations are emphasized as a primary factor in various tradeoff studies. Digital symbol generation is examined in terms of hardware functional, speed, and memory size requirements.

N76-17125 Royal Radar Establishment, Malvern (England). DIGITAL SCAN CONVERSION TECHNIQUES

T. Snowball and T. R. Berry In AGARD Electron. Airborne Displays Dec. 1975 19 p refs (For availability see N76-17107 OB -06)

The Digital Semiconductor Scan Converter, and the factors determining the storage capacity required are discussed in terms of sensor and display CRT resolution, picture texture and observer aculty. A versatile experimental digital acan converter with a one megabit storage capacity, having various modes of store organization and display presentation is described.

Royal Rader Establishment, Malvern (England). POLAR TO CARTESIAN AXIS-TRANSFORMING DIGITAL SCAN CONVERTERS

T. R. Berry and T. Snowball In AGARD Electron, Airborne Displays Dec. 1975 25 p ref (For availability see N76-17107 08-06)

Ways in which digital scan converters can improve on conventional radar display formats are examined and how a display can be extended to give presentations not previously available is shown. The major limitations of son converters based on shift registers are discussed, in particular where such converters are required to transform polar rader formats to rectilinear TV. It is then shown how the introduction of the fast semi-conductor random access Memory (RAM) has made the axis-transformation problem a relatively straightforward hardware implementation of conventional axis-conversion formulae. Special display and conversion problems associated with moving platform systems are outlined, and techniques for applying motional stabilization to the converter to facilitate scan to scan integration discussed. The organization of such ground stabilized converters to provide a choice of ground or platform stabilized displays are then described. Finally, the limitations of a simple system based on a single picture point update per store word access (spot at a time transfer) is considered, and a more complex organization which allows for more than one spot to be updated at a time is outlined.

N75-17127 Hughes Aircraft Co., Culver City, Celif. DIGITAL SCAN CONVERTERS IN AIRBORNE DISPLAY EYSTEMS

G. K. Slocum and J. O. Mysing (AFAL) In AGARD Electron. Airborne Displays Dec. 1975 18 p (For availability see N76-17107 08-06)

Recent developments in digital scan converters (DSC) provide high quality image storage for avoints sensor displays and can simplify the pilot's tasks in radar target acquisition. Typical digital scan converter concepts and their system design implications are described for an air-to-air radar, a multimode radar and a high resolution reconnaissance sensor. Studies of operator performance in using stored digital imagery with various encoded gray levels show eight shades of gray are adequate for radar imagery but at least 16 are needed for electro-optical imagery. Tradeoffs in memory selection and digital image enhancement techniques are presented. The cost of ownership analysis shows that the high reliability, low maintenance adjustments and short life cycle cost savings over analog scan converter display systems.

N76-17128 Marconi-Elliott Avionic Systems Ltd., Rochester (England). ECONOMIC SCAN CONVERSION TECHNIQUES FOR INTEGRATED AVIONIC SYSTEMS

G. C. Bull and G. M. Barling. In AGARD. Electron. Airborne Displays. Dec. 1975. Bip (For availability see N78-17107.08-06) Modern cookpit displays, systems are making increasing use of TV rester techniques to provide a common signal format for a wide range of differing types of compitted and sensor data. A principal feature of such systems is the necessary scan conversion units which should provide accurate translation of data and video picture inputs into the common raster display base. Earlier double ended scan conversion tubes have been found to have almost unacceptable problems in terms of accuracy, dynamic range and ploture registration. A new technique using a tube scan converter of the single electron gun type avoids many of the problems of the serilier double ended type and permits the conversion of

high resolution video pictures without the relatively high costs

of the large memory requirements of equivalent digital scan

converters. When however the conversion picture subject is limited in size, a new digital technique has considerably reduced the memory requirements compared with those necessary for video picture conversion. By relating the scan conversion technique to the particular task in hand, it appears probable that the cost of future scan converters can be reduced to a small proportion of the overall display system cost.

N76-17129 Draper (Charles Stark) Lab., Inc., Cambridge, Mass DISPLAY GENERATOR INSTRUCTION SET CONSIDERA-TIONS FOR AEROSPACE APPLICATION

Ivan S. Johnson and Stephen K. Holford In AGARD Electron. Airborne Displays Dec 1975 11 p refs (For availability see N76-17107 08-06)

A tradeoff study to determine desirable characteristics in a display procussor for an ierospace (space shuttle) application is reported. The assumed display device is a conventional CRT. The tradeoffs involved in specifying which instructions should be implemented in the display processor's hardware repertoirs or presented. The importence of such a tradeoff focuses primarily upon the resultant software costs (size, speed of execution, time to write and de-bug) incurred as a function of whether certain instructions are implemented in the processor hardware. Other factors are size, weight, reliability, processor/display unit speed relationships, and memory implications. The tradeoff study of possible graphics capability includes most of the instructions that an aerospace display generation scheme would be contronted with including vectors, alpha-numerics, beam control instructions

(e.g., blinking, dash lines, line width, etc.) index branch, subroutine call and return, compare and skip, rotation, windowing, and special items like moving tape meter.

N76-17130 EMI Electronics Ltd., Hayes (England). INTEGRATION ALGORITHM IN A DIGITAL DISPLAY STORE FOR AIRBORNE SURVEILLANCE RADAR V. B. Hulme In AGARD Electron. Airborne Displays Dec

1975 27 p refs (For availability see N78-17107 08-08)

A search for optimum integration algorithms in a multicell digital display processor for airborne surveillance and search radar is discussed. Markovian statistics are applied to evaluate performance in terms of probabilities of detection and false alarm Results are illustrated by probability graphs characterizing the alternatives examined and a selected range of parameters. The best are ranked in order of false alarm/detection probability ratio referred to this input, for a standard performance. It is concluded that algorithms employing a simple regular decrement are superior to proportional decrement algorithms or sum and dump integrators.

THE DAIS DESIGN AND SYSTEM INTEGRATION ASPECTS OF ELECTRONIC AIRBORNE CONTROLS AND DISPLAYS Nicholas A. Kopchick and S. Joel Premselast (Raedan Assoc. inc.) In AGARD Electron. Airborne Displays Dec. 1975 20 p refs (For availability see N76-17107 08-08)

The Digital Avionics Information System (DAIS) encompesses the maximum quilization of electronic airborne controls and displays to present to the pilot all pertinent and timely information necessary for both normal and degraded mission operations. The valient features include a description of the DAIS: (1) operational and system requirements, (2) control/display subsystem configuration and functional operation, and (3) system and subsystem life-cycle cost considerations. Through the increased use of common digital avionic equipments and software modules, an effort is being made in this program to directly attack the problem of rising life-cycle costs while, at the same time, maintaining or increasing given performance levels. Results of recent DAIS design studies and system analyses, based on typical close air support and air superiority missions, conducted by the Air Force Avionics Laboratory are presented.

J R Muchin In AGARD Electron Airhorne Displays Dac 1975 10 p ref (For availability see N78-17107 08-08)

Head up display systems incorporating general purpose digital computers are now in wide scale operational service and their effectiveness and reliability have been demonstrated in over 1,000,000 flying hours. Later developments of this type of system have expanded the role of the HUD computer to include many weapon alming functions which have considerably improved weapon delivery affectiveness particularly in the air to air modes The fire control system of the YF16 prototype air combat fighter is one of the most recent systems of this type and has proved highly effective in the Edwards AFB fly-off. The latest example of this type of system is the Marconi-Elliott 664 which further extends the capabilities by the use of a fast 8K, 16 bit computer This equipment uses MSI and LSI technology and offers a significantly increased range of weapon delivery modes at a comparable cost to earlier simple HUD systems: Author

THE APPLICATION OF ELECTRONIC AND COMBINED DISPLAYS TO GROUND MAPPING AND NAVIGATION W. H. McKinlay /n AGARD Electron. Altborrie Displays Dec 1975 5 p (For availability see N76-17107 08 08)

The evolution is reviewed of navigation displays and the growth of their pictorial content. Civil and military requirements are treated. Examples of a pictorial display for transport aircraft, and a Combined Display including topographical data for military aircraft are presented. Problems of data storage and the increasing need for color are mentioned. The combined display for military aircraft is introduced and it is pointed out in particular that it permits an evolutionary approach by pilots because it retains topographical data, yet presents many new possibilities because of its versatile electronic element. Some possible future developments are mentioned and the conclusion is drawn that certain real operational constraints may be as significant as the availability of more flexible technologies.

ELANDIS: A VERTICAL SITUATION DISPLAY
Wolfgang Holstein In AGARD Electron, Alrborne Displays Dec.
1975 6 p. refs (For availability see N76-17107 08-06)

An interim report of a study of display requirements for final approach management of STOL-sircraft is presented. The proposal of this electronic landing display (ELANDIS) is based on the perspective view of the vertical situation of STOL-sircraft in landing. The concept ellows a continuous surveillance of the automatic landing system and provides sufficient information which enables the pilot to carry out the landing manually (if desired or necessary in case of failure). Furthermore there is a brief description of the hardware configuration of the hybrid simulation system (HSS). In its present state the HSS consists of an analog computer EA1 580, a digital computer PDF-11/20, a graphic display terminal GT 40, a simulation cockpit and a magnetic tape station MBS/Ampex. The software concept gives a general view of the distallow.

ASTROLABE, AN INTEGRATED NAVIGATION AND LANDING AID SYSTEM: ON BOARD AND GROUND DISPLAY OF INFORMATIONS

Jacques Dorey and Guy Ringenbach: In AGARD Electron. Airborne Displays Dec 1975 8 p refs in FRENCH; ENGLISH summary (For availability see N76-17107 08-06)

ONERA is developing a microwave localization system, based on the properties of synthetic antennas, which permits the two-dimensional (azimuth and elevation), simultaneous analysis of large number of targets made of low power bascons. This system ensures alrepace surveillance, and at the same time provides the pilot with a visualization of the surrounding terrain (a.g. runway boundaries) with the proper perspective. It permits the integration of various functions of ground control necessary to the pilot in blind navigation. The data processing and display devices are described associated with this system; an optic device, and an integrated digital device. The results are analyzed, and the application possibilities of the system are presented. Author

A MULTI-SENSOR MULTI-FUNCTION DISPLAY FOR THE PANAVIA MULTI-ROLE COMBAT AIRCRAFT

D. W. Hussey In AGARD Electron, Airborne Displays Dec 1975 12 p (For availability see N76-17107 08-08)

The weapon system operator's principal access to the wide range of raw sensor and processed data available on the MRCA was implemented by the development of an integrated eleutronic display system. The equipment is one of the first to solely utilize a standard television rester to display both synthetic tabular and graphical data in a form directly compatible with EO Sensor television video signals. An electronically labelled multifunction keyboard allows the crew member to access and update the computing system data in a wide variety of modes using the minimum of controls and panel space. The generation of synthetic symbols directly in the rester by modulation of the video signal is achieved by a novel form of time-shared digital techniques providing high accuracy and resolution with a considerable economy of hardware. A particular feature of the system is the elimination of staircasing of the raster generated graphics. Other aspects include the achievement of high resolution and contrast under conditions of extreme cookpit ambient illumination. The system forms the basis of a new range of head down displays which are being developed for a wide range of military aircraft types. Author

CHARACTERISTICS OF HEAD-UP DISPLAY SYSTEMS [CARACTERISTIQUES DU COLLIMATEUR DE TIR ET DE PILOTAGE (HUD)]

M. Martin In AGARD Electron, Airborne Displays Dec. 1975 4 p. in FRENCH (For availability see N75-17107 08-06)

Development of second-generation head-up display systems coupled to large capacity computers that may provide not only a complex visual presentation but may also undertake all computations required for air-to-air and air-to-ground firing was reviewed. Further Applications of head-up display systems to civil aviation, primarily in relation to blind flying near ground level (automated landing approach) were also discussed. It was shown that the problem of integrating the computation and symbol generation functions for both military and civil applications may be treated similarly, although military applications tend to be more complex. A general purpose computer with a capacity of 5000 16 bit words would be adequate for these applications.

A PROGRAMMABLE RASTER-BASED DISPLAY SYSTEM FOR USE WITH ELECTRO-OPTICAL SENSORS

R. G. White (Marconi Elliott Avionic Sys. Ltd.) In AGARD Electron. Airborne Displays Dec. 1976 9 p refs (For availability see N76-17107 08-06)

An experimental sirborne, programmable rester-based electronic display system is presented, capable of generating a variety of symbology and superimposing this on a picture of the outside world provided by a forward looking daylight or low light television camera. Examples of the symbology which can be generated by the display system are described in particular the initial symbology chosen for flight trails to investigate the potential of night vision sensors for low level, high speed flight at night. The philosophy of superimposing flight information on the picture from a night vision sensor is discussed, and it is concluded that superimposed symbology is necessary if an aircraft's night time capability is to be effectively extended.

WILL THE FUTURE ELECTRONIC AIRBORNE DISPLAY BE STEREOSCOPIC?

R. Stark In AGARD Electron, Airborne Displays Dec. 1975 17 p. refs (For availability see N76-17107 08-06)

Research into a method of air traffic con. ol aimed at the realization of a cockpit display which permits the pilot to participate actively in air traffic control is reported. The goal was the three-dimensional representation of airways and aircraft shead, as seen by the pilot. The working conditions of the pilots were examined with the aid of a simulator and scenes featuring relevant traffic situations were shot for a 3D-film. The pilot depends on a microcomputer and a color display unit for the method proposed. Data supplied by ground stations and airborne sensors are stored and processed on-line, i.e. in step with the picture data. For this purpose the object coordinates are transformed to the aircraft position and projected onto the picture screen separately for the left and right eyes. The mathematics, simulation equipment and simulation programs are described. The time requirements and the volume of data transmitted and processed are assessed. The results favor a stereoscopic display.

THE MALCOLM HORIZON K. E. Molecolm, and P. J. Anderson In its Visual Presentation of Cockpit Information Including Special Devices Used for Particular Conditions of Flying Nov. 1976 3 p ref (For primary document see N77-16050 07-08) Avail: NTIS HC A05/MF A01

The Malcolm Horizon is a bar of light which shines across the instrument panel of an aircraft cockpit driven by motors so as to move in a manner corresponding to the real horizon outside the alicraft. The motion is controlled by servo-motors which are driven by signals derived from the gyro platform of the stroraft. A series of simulator trials and flight trials have been carried out on the device in an attempt to evaluate it and further develop it, and to evaluate aircraft performance while using the device. The trials showed that the bar of light is very compelling, is in constant view regardless of where the gaze may be directed and does not interfere with the normal reading of the instruments. All of the pilots who have flown with the Malcolm Horizon reacted positively and would welcome the addition of this device to the cockpit.

TERRAIN FOLLOWING USING STEREO TELEVISION In AGARD Visual Presentation of Cockpit Information Including Special Devices Used for Particular Conditions of Flying Nov. 1876 10 p. refs (For primary document see N77-18050 07-08) Avail: NTIS HC A05/MF A01

An experiment was conducted to determine whether low altitude, terrain following flight could be accomplished better with stereo television than with conventional two-dimensional television. Nine subjects, both pilots and nonpilots flew a simulated F-4 aircraft using only the information supplied by an air-to-ground television system. The simulation system consisted of 12: by 30-foot, 2,000 1 scale terrain model, a gantry system carrying the television camera, a moving base cockplt, and associated computer hardware that provided the proper control stick responses. The subject's task was to fly as low as possible across a 9 mile flight corridor without going below 250 feet above ground level. A single path that varied from sea level to 4,000 feet and at a constant suspend of 300 knots was flown by all subjects. The subjects could control only the vertical dimension of the aircraft's flight.

MATRIX ELEMENT DISPLAY DEVICES AND THEIR APPLICATION TO AIRBORNE WEAPON SYSTEMS

/n AGARD Visual Presentation of Cockpit Information Including Special Devices Used for Particular Conditions of Flying Nov. 1976 8 p. refs (For primary document see N77-16080-07-08) Avail: NTIS HC A05/MF A01

The impact of two important matrix display design variables on tactical target recognition performance is discussed. Element density (i.e., the number of individual display resolution elements per degree as viewed by the observer) and the percent active area on the display surface were experimentally manipulated by adjusting the viewing distance from a rear projection screen over which a grid mask was placed. The targets were presented to subjects using zoom linagery at a simulated signt range which initially precluded recognition. As the target size increased subjects were asked to press a remote projector control button when they were virtually certain of the correct response. The results indicate little effect of percent active area li.e., down to 56 percent) on target recognition performance for element angular subtense values between 0.75 and 3.0 minutes of arc (corresponding to element densities of from approximately 165 to 40 elements per inch at a 28 inch viewing distance). The effects of element density, however, were large and conformed to expectations derived from the limiting resolution of the visual system Geometric mathematical derivations are provided for the relationships between element density, viswing distance, target size, sensor field of view, total number of display elements and slant range at time of target recognition

A THEORETICAL FRAMEWORK TO STUDY THE EFFECT
OF COCKPIT INFORMATION

In AGARD Visual Presentation of Cockpit Information Including Special Devices Used for Particular Conditions of Flying Nov. 1976 7 p refs (For primary document see N77-16050 07-08) Avail NTIS HC A08/MF A01

A theoretical framework is presented, describing human operator's participation in manned vehicle systems. The human operator is described in terms commensurate with those used for other system elements, which is desirable because of the complex intersection between human functioning and his task environment (e.g., cockpit information). The result is an integrated model of the man machine situation serving as a diagnostic tool (for existing systems) and allowing the extrapolation to new situations. The theoretical framework deals with manned vehicle systems involving the human operator performing continuous control and/or decision making tasks. It will be illustrated how the effect of cockpit information (e.g., type, quality and interference of displayed information, both visual and suditory) on human functioning and mission success can be operationalized and straightforwardly investigated.

COMPARATIVE APPRAISAL OF PROPULSION SYSTEMS FOR VTOL-AIRCRAFT

Heinrich Leibach In AGARD V/STOL Propulsion Systems Jan 1974 19 p (For availability see N74-20401 11-28)

An engine-oriented method for a functional description and classification of all existing and future alroraft jet propulation systems is presented. It is assumed that all aero propulsion systems are made up of assemblies which carry out the thrust generation, thrust augmentation and thrust control functions, with various principles of operation being possible, as well as various combinations of the said assemblies. If these three fundamental functions are determined symbolically and free-of-value, it will be possible to obtain a basic description and a classification of all existing and future engines, via the determination of the energy flows. Moreover, this classification method will permit derivation and description of new, unconventional power plants.

INVESTIGATION OF THE RELATIVE MERITS OF DIFFERENT POWER PLANTS FOR STOL-AIRCRAFT WITH BLOWN FLAP APPLICATION

H Grieb, W. Kluszmann, and G. Weist In AGARD V/STOL. Propulsion Systems Jan 1974 19 p refs (For availability see N74-20401 11-28)

The, relative merits of different air supply systems for STOL-aircraft with blown flap application are investigated. Under consideration are self-sustained supply units, such as gas turbine driven compressors, remote compressors driven with hot gas from the cruise engines and 2 possibilities for off-take of compressed air from the cruise engines. The nir supply systems reviewed are compared with respect to the design requirements. the operating behaviour including any reactions on the cruise engines, the sensitivity to component failure and the weight penalty to be expected.

N74-20407 Royal Aircraft Establishment, Bedford (England) THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE EXTERNAL-FLOW, JET-AUGMENTED FLAP
P. R. Ashill In AGARD V/STOL Propulsion Systems

1974 18 p refs (For availability see N74-20401 11-28)

Theoretical methods for calculating the forces and moments acting on wings with external-flow, jet-augmented flaps are discussed. One of the simplest of these relies on the analogy between the internal-flow, jet flap and the external-flow, jet flap. To date, this method has been limited in application by its reliance on either measured or assumed value of the jet-deflection angle and the thrust-recovery factor, i.e. the factor that is applied to the momentum flux leaving the exit of the engine nacelle to allow for turning and spreading losses. This paper is concerned with a semi-empirical method for predicting these parameters. The method is based on an analysis of a series of tests performed

THE COURSE OF THE PARTY OF THE

on a wing, body and injector-powered nacelle under static conditions. The formulas derived from the analysis are combined with a theory, which is based on the jet-flap analogy, to provide estimates of the forces and moments acting on wings with external-flow, jet-augmented flaps in forward flight Comparisons are made between this method and wind-tunnel data obtained from tests performed at the RAE and elsewhere.

N74-20408 Flat S.p.A., Turin (Italy). Div. Avlazione ENGINE CYCLE SELECTION FOR COMMERCIAL STOL AIRCRAFT

Giorgio Feo and Alfredo Capuani (Societa Aeritalia, Turin). In AGARD V/STOL Propulsion Systems Jan 1974 11 p (For availability see N74-20401 11-28)

The cycle and design parameters partinent to a turbofan to be used for STOL short haul applications have been studied. For the chosen strarest configuration, the criteria that condition the choice of the cycle, listed in decreasing importance, have been determined as follows: (1) low noise level. (2) high specific thrust to obtain low-weight and reduced-size engines, and (3) low specific fuel consumption (s.f.c.). It is concluded that the controlling factor is the noise level requirement for sirports in congested areas. In order to satisfy this and the mission operational requirements the turbofan engine is driven towards medium bypass ratios and high thrust weight ratios but with less emphasis on

N74-20409 Deutsche Forschungs- und Versuchsanstalt füer Luft- und Raumfahrt. Goettingen (West Germany) WIND TUNNEL TESTING WITH ENGINE SIMULATION FOR

V/STOL AIRPLANES R. Wulf and E. Melzer III AGARD V/STOL Propulsion Systems Jan. 1974 14 p. refs (For sysilability see N74-20401 11-28)

For the development of STOL and expecially for VTOL airplanes with modern engines, wind funnel testing with adequate jet and engine simulation is of great importance. Current engine systems are classified. Their main characteristics concerning the aerodynamic interference between engine and airplane or between engine and the surrounding flow field are described. Based on these aspects suitable simulation systems are discussed. The power requirement for exact simulation is estimated and in the case of compressed air supply the influence of pressure ratio and temperature is shown. Some simulators developed and used in the last few years illustrate the different testing techniques. for compressed air blowing, ejectors, and tip turbine driven fans. Concluding remarks present some proposals for a future collaborative program of work in the field of engine simulation.

RECENT TECHNOLOGY ADVANCES IN THRUST VECTOR-ING SYSTEMS

Richard P. Taylor and Joseph A. Londer In AGARD V/STOL Propulsion Systems Jan. 1874 11 p. refs (For availability see N74-20401 11-2B)

The important technical challenges that must be overcome in order to make a reality of thrust vectoring of an afterburning engine for a multi-mission aircraft. Two approaches to vectoring - with and without afterburning in lift are described which have been developed to the point that they are available for direct application to an engine development program. In addition, the evaluation/selection/design criteria for vectoring systems have developed to the point where specific design and configuration gonsiderations that are peculiar to VTOL are identified and reasonably well understood. Thus, although the engine and aircraft industry continue the search for and development of even better thrust vectoring systems and installations, it is nonsidered that the fundamental technology and knowhow is available to proceed with a thrust vectored, afterburning engine and sircraft.

SHORT HAUL AIRCRAFT ADAPTATION TO THE USE OF SHORT LANDING FIELDS (ADAPTATION MOTEURS-CELLULE DES AVIONS COURTS COURRIERS UTILISANT DES PISTES COURTES)

Plerre Guyot In AGARD V/STOL Propulsion Systems Jan 1974 11 p In FRENCH (For availability see N74-20401 11-28)

The results of an engine/airframe optimization study carried out in order to investigate the effect that field length has on aircraft weight and direct operating costs are given. The study uses an aircraft with a fixed passenger load, flight plan and aerodynamic characteristics, and an engine with a fixed gas generator. The two main parameters are then wing loading and bypass ratio, it was concluded that there is a considerable penalty in operating costs for shortening the field length.

BASIC RESEARCH REQUILEMENTS FOR VISTOL PROPUL-

SION AND DRIVE-TRAIN COMPONENTS

John Acurio In AGARD V/STOL Propulsion Systems Jan.

1974 14 p (For evallability see N74-20401 11-28)

The design of aircraft engines for use with V/STOL aircraft is discussed. Emphasis is placed on the serodynamic components of the engine. The subjects discussed are as follows: (1) general requirements, (2) compressors, (3) turbines, (4) combustors, and (5) drive train concepts. Graphs of engine performance under various operating conditions are provided.

N74-20413 Deutsche Forschungs- und Versuchsenstelt füer Luft- und Raumfahri, Porz (West Germany). AER ODYNAMIC INTERPERENCE BETWEEN FUSELAGE AND LIFTING JETS EMERGING FROM ITS LOWER PART

G. Viehweger In AGARD V/STOL Propulsion Systems Jan. 1974 14 p refs (For availability see N74-20401 11-28)

In a basic experimental study on a cylindrical fuselage, the change in lift and pitching moment induced by two lifting jets of high velocity, situated one behind the other, is determined. The constructional principle of the model permits a wide variation of fuselage length, of the distance between the jets and the diameter of the jet nozzles. As aerodynamic parameters the engle of attack, the location of a wing relative to the jet nozzies, the mainstream and the jets velocities are varied within a wide range. The pressure distribution on the whole surface of the cylindrical fuselage central section is measured. The results provide a survey on the influence of the different parameters. The aerodynamic problems are discussed. The experimental installation and the performance of the tests are described.

N74-20414 Army Air Mobility Research and Development Lab., RESEARCH TOWARD DEVELOPMENT FEASIBILITY OF AN ADVANCED TECHNOLOGY V/STOL PROPELLER SYSTEM

James Gomez, Jr. and Robert M. Levintan In AGARD V/STOL Propulsion Systems Jan. 1974 12 p. refs. Prepared in cooperation with Hamilton Standard Div., United Aircraft Corp., Windsor Locks, Conn. (For availability see N74-20401 11-28)

Analytical studies and limited hardware efforts have shown that improvements can be obtained in V/STOL propeller components through the use of improved materials and new concepts. Several of the design concepts which evolved from a baseline feasibility study were explored. Some have been partially proven and others require significantly more research than anticipated. Laboratory test work to date on the boron-aluminum blads spar indicates that the material characteristics are ideal for a propeller environment. However, the efforts expended for research on titanium gear tooth coatings have indicated that much more research is necessary.

THE INFLUENCE OF THE CONTROL CONCEPT FOR V/STOL ENGINES ON THEIR STATIC AND DYNAMIC PERFORM-ANCE CHARACTERISTICS

K. Bauerfeind and G. Doepner In AGARD V/STOL Propulsion Systems Jan. 1974 13 p. refs (For availability see N74-20401

The decrease of total thrust and the changes of important angine parameters of two-spool bypass engines caused by bleeding air lipstream of the combustion chamber for stabilizing and for maneuvering. VTOL-aircraft in the hover or transition phase have been investigated. A variation of the engine design parameters turbine inlet temperature, total pressure ratio and bypass ratio has been considered. In each case three different control concepts have been applied: (1) the power lever position calls for a constant fuel flow, (2) the power lever position calls for a constant HP-compressor speed, and (3) the power lever position calls for a constant turbine inlet temperature. The smallest decrease in total thrust results when the HP-compressor speed is kept constant, when the total pressure ratio is 20 or above and the

bypass ratio is between 2 and 10. The design turbine inlet temperature only has a minor effect on this. But, on the other hand, the increase of turbine inlet temperature due to bleeding air is very high. The biggest decrease in total thrust occurs when the turbine inlet temperature is kept constant by the control system and when the engine has a high bypass ratio and also a high design turbine inlet temperature.

N74-20416* National Aeronautics and Space Administration Ames Research Center, Moffett Field, Calif. INTEGRATED PROPULSION/ENERGY TRANSFER CON-TROL SYSTEMS FOR LIFT-FAN V/STOL AIRCRAFT Wallace H. Deckert and L. Stewart Rolls. In AGARD V/STOL Propulsion Systems Jan. 1974 8 p. refs (For availability see N74-20401 11-28)

An integrated propulsion/control system for lift-fan transport aircraft la described. System behavior from full-scale experimental and piloted simulator investigations are reported. The lift-fan transport is a promising concept for short-to-medium haul civil transportation and for other missions. The lift-lan transport concept features high cruise airspeed, favorable ride qualities, small perceived noise footprints, high utilization, transportation system flexibility, and adaptability to VTOL, V/STOL, or STOL configuretions. The lift-fan transport has high direct operating costs in comparison to conventional aircraft, primarily because of propulsion system and aircraft low-speed control system installation requirements. An integrated lift-fan propulsion system/sircraft low-speed control system that reduces total propulsion system and control system installation requirements s discussed.

N74-20417 Pratt and Whitney Aircraft, East Hartford, Conn. V/STOL DEFLECTOR DUCT PROFILE STUDY

R. I. Strough and T. A. Wynosky /n AGARD V/STOL Propulsion
Systems Jan. 1974 13 p (For availability see N74-20401

V/STOL deflection of exhaust gases creates static pressure gradients within defientor system dusting which propagate upstream and produce a nonsymmetric back-pressure distribution on the fan. Depending on the deflector design, the fan will experience a higher-than-average back-pressure at one point in the duct, and lower-than-average pressure near the deflector. If this back-pressure distortion is severe enough, engine stability can be compromised. Experimental and analytical studies were conducted to study the back-pressure distortion problem. Small-scale cold flow inodels of various deflector devices were tested to obtain a parametric mapping of the back-pressure disturbance as a function of bypass ratio, duct Mach number, and deflector geometric parameters. Screens of verying solidity were used to generate total pressure gradients around the rivot similar to those generated by the fan. The parametric distortion patterns were then duplicated on a specially designed full-scale fan test rig, and fan aurye maigin degradation was related to the generated back-pressure profile. The final analysis resulted in the formulation of design ground rules which establish criteria for the disturbance proximity and magnitude that current turbomachinery can tolerate.

N74-20418 Societe Nationale d'Etude et de Construction de Moteurs d'Aviation, Villaroche (France). LOW SPEED TURBINE GEAR BOX TURBINE LENTE CONTRE BOITE D'ENGRENAGES Victor Benalmhon In AGARD V/STOL Propulsion Systems Jan. 1974 17 p. in FRENCH (For availability see N74-20401 11-28)

A propulsion system is proposed where a low speed highly loaded turbine driven by two gas generators is coupled directly to the rotor shaft, thus avoiding the heavy gear box. A description is given of the mechanical and aerodynamic characteristics of this propulsion system and its capability to meet the requirements various operating conditions, including high speed flight with propulsion support by the turbulats used as gas generators for the rotor turbine. The system described is compared with a conventional propulsion system with respect to fuel consumption and maintenance cost. Author

COMPACT THRUST AUGMENTORS FOR V/STOL AIR-CRAFT

Brian Quinn In AGARD V/STOL Propulsion Systems 1974 12 p refs (For availability see N74-20401 11-28)

AIRCRAFT PROPULSION AND POWER

The prospect of undertaking V/STOL and cruise flight with the same powerplant has considerable appeal and can be achieved by proper use of thrust augmenting ejectors. Proper use requires an ejector that simultaneously satisfies two conflicting requirements; high performance and installation compactness. In addition to elementary design considerations, the following paragraphs discuss the loss mechanisms to which augmentors are most sensitive and describe how they may be manipulated to produce high levels of thrust sugmentation in ejectors suitable for V/STOL aircraft. Conclusions are corroborated by the results of experimental investigations of the effects of geometric constraints on the flow structure and performance of thrust augmenting ejectors.

THRUST PERFORMANCE OF PODDED LIFT-FANS IN CROSSFLOW

R. A. Tyler and R. G. Williamson in AGARD V/STOL Propulsion Systems Jan. 1974 14 p refs (For availability see N74-20401 11.28)

Experimental data relating to the thrust performance in crossflow of single, individually podded, lift-fans are discussed. Various 15-inch tip diameter fan arrangements were tested over a range of grossflow velocity ratio typical of the transition flight profiles of proposed lift-fan aircraft. Each model was operated in isolation in a manner allowing fan thrust (efflux momentum) to be assessed directly from force-balance measurements. The relevant transition conditions, in association with practical dimensional restrictions on intake geometry for separately cowled fans (in, for instance, multiple in-line arrangement) suggest that lip flow separation could be an important feature of the inflow distortion arising from crossflow. In such circumstances thrust deterioration with increasing crossflow velocity is appreciable. The measured data illustrate the influence on fan thrust sensitivity to crossflow of various installational features including fan operating point, cowi lip radius, inlet axial depth, and crossflow Author

SOME ENGINE AND AIRCRAFT DESIGN CONSIDERA-TIONS AFFECTING NOISE

D. R. Higton and T. A. Cook (Roy. Aircraft Estab., Farnborough, Fngl.) In AGARD V/STOL Propulsion Systems Jan. 1974 9 p ref Prepared in cooperation with Roy. Aircraft Estab., Fernborough, Engl. (For availability see N74-20401 11-28)

The general prospects for further reductions in engine noise are reviewed. The factors which determine the best combination of engine specific thrust [or by-pass ratio] and complexity of acoustic treatment are assessed. The effect of design require-ments, particularly that of field length, on aircraft noise and economics is then discussed, together with the prospects for manipulating airframe design parameters in order to reduce noise. Quantitative consideration of noise shielding is not included; this can be regarded as an important effect meriting a separate study. Some of the interactions between engine and alreraft design as they affect the economics and noise of conventional short range aircraft for short to medium field lengths are analyzed.

N74-20422* National Aeronauties and Space Administration. Lewis Rossarch Center, Cleveland, Ohio. INFLUENCE OF NOISE REQUIREMENTS ON STOL PROPUL-SION SYSTEM DESIGNS

Raymond J. Rulis In AGARD V/STOL Propulsion Systems Jan. 1974 17 p refs (For availability see N74-20401 11-28)

The severity of proposed noise goals for STOL systems has resulted in a new design approach for aircreft propulsion systems it has become necessary to consider the influence of the noise goal on the design of engine components, engine systems, and the integrated nacelle, separately and collectively, from the onset of the design effort. This integrated system design approach is required in order to effect an optimization of the propulsion and aircraft system. Results fron- autensive design studies and pertinent test programs are presented which show the effect of noise specifications on component and system design, and the trade-offs possible of noise versus configuration and performance. The design optimization process of propulsion systems for powered lift systems is presented beginning with the component level and proceeding through to the final integrated propulsion system. Dasigns are presented which are capable of meeting future STOL noise regulations and the performance, installation and economic penalties are assessed as a function of noise level.

THE INFLUENCE OF NOISE REQUIREMENTS ON STOL
AIRCRAFT ENGINE DESIGN

D. G. M. Davis In AGARD V/STOL Propulsion Systems Jan. 1974 11 p. refs (For availability see N74-20401 11-28)

The noise regulations applicable to STOL aircraft are discussed. It is stated that the current aircraft fail to meet the noise regulations and that a reduction of 10 to 15 PNdB must be achieved. An even greater reduction of 25 to 30 PNdB is required to make the aircraft auceptable to city center STOL landing areas. Aircraft performance parameters and flight path considerations which will contribute to a reduction in noise levels are described. A turbofan engine of relatively high hypass ratio fitted with a variable pitch fan is proposed as the basic power plant.

NOISE CHARACTERISTICS OF AN EXPERIMENTAL LIFTING FAN UNDER CROSSFLOW CONDITIONS
G. Krishnappa In AGARD V/STOL Propulsion Systems Jan. 1974 14 p. refs (For availability see N74-20401 11-28)

The results of acoustic tests conducted on a 12-in, diameter model lifting fan, to find the effect of crossflow on its noise redistion characteristics are presented. The broadband noise levels increased with the velocity of the crossflow. The fundamental blade passing frequency and its second harmonic tones showed moderate changes in the field shapes and levels for low crossflows. At high crossflow velocities due to the presence of a partial stalled region the tone levels increased drastically. The tones generated by the rotor blades due to inflow distortions were believed to dominate over the rotor and stator interaction levels. At fan speeds close to the design point, there were only slight changes in the tone levels and field shapes at the blade passing frequency as the blade incidence excursions became less severe and rotor and stator interaction was much stronger. However, at the higher crossflow velocities the second harmonic tones showed substantial reductions in tone levels with different field shapes.

N74-20427 Detroit Diesel Allison, Indianapolis, Ind COST OF OWNERSHIP FOR PROPULSION SYSTEM OF POWERED LIFT AIRCRAFT

W. L. McIntire In AGARD V/STOL Propulsion Systems Jan. 1974 20 p. refs (For availability see N74-20401 11-28)

A discussion of the relationship of advanced propulsion technology for powered lift V/STOL aircraft and the elements of cost of ownership development, acquisition, and operation and maintenance is presented. Competitive demonstrator programs, component technology versus aircraft, and mission

requirements and implementation of design-to-cost programs are discussed an basic cost considerations for the development program element of cost of ownership. Production requirements and manufacturing methods required for new materials and advanced serodynamic components are presented as the second cost of ownership parameter to provide acquisition costs effectively balanced with performance and cost. Finally, system performance, reliability, and maintainability are evaluated to ensure that the total cost of ownership is commensurate with the job to be done.

THE DEVELOPMENT OF AN INTEGRATED PROPULSION SYSTEM FOR JET STOL FLIGHT RESEARCH

J. A. Conway In AGARD V/STOL Propulsion Systems Jan. 1974 15 p refs (For svailability see N74-20401 11-28)

The Augmentor-Wing powered lift concept provides the high lift required for STOL terminal operations by means of a close interrelationship between the propulsive and aerodynamic functions of the system. Therefore, the propulsion system is subject to more extensive design requirements than a conventional engine Installation. Subsequent to extensive large scale model testing of the concept, general agreement was reached that flight research was feasible and desirable, but in view of the long development times and high costs involved, particularly in respect to engines, means would have to be found to utilize both existing engines and airframe. A de Havilland Buffalo airframe became the basis of the Augmentor-Wing flight research aircraft. The selection, modification and testing of the Holls-Royce Spey 801 SF which became the basic power plant for the research aircraft are discussed. A description of the associated augmentor ducting is also given, together with an outline of the propulsion aspects of the first phases of testing.

THE DEVELOPMENT AND FLIGHT TESTING OF THE PROPULSION SYSTEM OF THE VAK 191 B V/STOL STRIKE AND RECONNAISSANCE AIRCRAFT Klaus Wielend // AGARD V/STOL Propulsion Systems Jan.

Klaus Wieland /ri AGARD V/STOL Propulsion Systems Ja 1974 12 p (For availability see N74-20401 11-28)

The VAK 191 B has a mixed propulsion system comprising a main lift/cruise engine in the fuselage center and two lift engines installed in the front and the rear section of the fuselage. Blend air is taken from each engine for aircraft attitude control. Design and development of the propulsion system including the control bleed system will be discussed. The type of control for the propulsion and bleed air system plays an important role towards achieving maximum performance. Extensive model testing has been done to investigate main and lift engine intake performance, lift engine relight capability and hot gas reingestion characteristics of the aircraft. The results have been proven in ground and flight testing. Full scale testing of the bleed air system has been carried out to derive steady state and dynamic obsrecteristics. During ground and flight testing with three prototypes performance, handling and reliability of the propulsion system under VTOL and transition conditions were investigated. Some special results and comparison with predictions are prasented.

DISTORTION INDUCED ENGINE INSTABILITY

Oct. 1974 182 p refs Lecture series held at London, 7-8 Nov 1974, at Wright-Patterson AFB, Ohio. 11-12 Nov. 1974, and Philadelphia, 14-15 Nov. 1974

Philadelphia, 14-15 Nov. 1974 (AGARD-LS-72) Avail NTIS HC \$7.00

The design criteria for jet aircraft engines and turbomachinery to obtain minimum airflow distortion and engine instability is discussed. The sources of distortion are identified. The aerodynamic and mechanical response of selected engines under distorted flow conditions are analyzed. Techniques for predicting and measuring the stability of an engine are described. Methods for increasing the tolerance of the engine to distorted flow in order to obtain more stable operation are explained. For individual titles, see N75-12955 through N75-12961.

N76-12955 Naval Postgraduate School, Montersy, Calif. INTRODUCTION TO DISTORTION INDUCED ENGINE INSTABILITY

Allen E. Fuhs /n AGARD Distortion Induced Eng. Instability Oct. 1874 19 p. refs (For availability see N75-12954 04-07)

Propulsion system instability, which may be caused by distorted inlet flow, is a recurring problem which must be solved in each new alroaft development program. Trends in engine and airframe design that keep distortion sensitivity as a continuing problem are discussed. Sources of inlet flow distortion are catalogued. This information is used to assess the potential difficulties in development of a variety of aircraft types. Methods for describing distortion both experimentally and conceptually are introduced. Sufficient beokground is stated to provide a perspective of the lecture series.

SOURCES OF DISTORTION AND COMPATIBILITY

R. Bouillet and J. M. Brasseur *In* AGARD. Distortion induced Eng. Instability. Oct. 1974. 11 p. refs. (For availability see N75-12954-04-07).

An analysis of the sources of flow distortion and operating compatibility for jet aircraft engines was conducted. The aspects of flow distortion considered are: (1) various operating cases of air intakes. (2) air intake design and engine compatibility. (3) test facilities required to compensate the lack of theoretical data and to confirm predictions, and (4) typical examples of air intake modifications aiming at significant improvement of the internal flow. The conditions of operation considered are normal operation in which the velocity field around the aircraft in an assumed infinite atmosphere is the only factor considered, and operation under conditions of disturbances from ground effect.

AEROMECHANICAL RESPONSE

F. Sisto In AGARD Distortion Induced Eng. Instability Oct 1974 13 p. refs (For availability see N75-12954 04-07)

Physical mechanisms are discussed which lead to the acromechanical response of sala-flow fan and compressor components when these mechines operate with a distorted inlet flow. Steady response of blades, venes and discs are considered briefly. Forced excitation of rotating components are treated. The specific form of the exciting gusts are elucidated. Self-excited vibrations of rotor blades and stator venes are considered as stemming from the general degradation of flow with distortion. Shaft and disc vibrations are also discussed as possible seromechanical responses to distorted flow. The role of various forms of damping and the use of composite materials are described with attendant problems in application through design. Remedial action available to the aeromechanical engineer is discussed with the objective of ameliorating the adverse effects of discorted-induced structural response.

YEST TECHNIQUES, INSTRUMENTATION, AND DATA PROCESSING

William G. Schweikhard In AGARD Distortion Induced Englinstability Oot 1974 43 p. refs (For availability see N75-12954 04-07)
CSCL 21E

Procedures for determining the effects of dynamic distortion on engine atability are analyzed. The test techniques, methods and types of instrumentation, and data processing functions are described. The advantages and limitations of various methods.

are reported. It is emphasized that ground facility tests are only a simulation of the flight environment, that instrumentation provides only a partial representation of the physical phenomena, and that poorly organized data processing procedures can impede and even distort the final result.

N75-12961 Pratt and Whitney Aircraft, East Hartford, Conn. METHODS TO INCREASE ENGINE STABILITY AND TOLERANCE TO DISTORTION

A. A. Mikolajczak and A. M. Pfeffer. In AGARD. Distortion Induced Eng Instability Oct 1974 17 p refs (For availability see N75-12954 04-07)

Techniques used during engine design which ensure stable engine operation over the complete flight envelope of the aircraft in which it is installed are discussed. Adequare stability margin is required to allow for the expected levels of inlet distortion. engine to ongine variations, engine aging and excursions of compressor operating lines during transients. Since the stability margin can be increased by raising the surge line of a compressor. increasing its tolerance to inlet distortion and modifying the design to reduce the sensitivity to transients, all these topics are treated in some depth. Emphasis is placed on the design for adequate stability margin and minimum penalty in engine fuel consumption, cost and weight.

SECONDARY POWER SYSTEMS FOR ADVANCED ROTOR-CRAFT

Raymond G. Smith (Boeing Vertol Co., Phila. Pa.) Feb. 1975 94 p refs

(AGARD-AG-1106; AGARDograph-206) Avail: NTIS HC \$4.75 The results are presented of a review of European manufactured Secondary Power Systems (SPS) for rotorcraft. A compilation of SPS functions, parametric SPS component data for optimization trade studies, and a trade study to select on optimum SPS are presented. The study addresses the aspects of integrated SPS (electrical, hydraulic, pneumatic and mechanical) concepts for cockpit and avionics environmental control systems, the protection system, holst drive system, main engine starting, auxiliary power unit and its starting system integration. System optimization and recommended selection are based on trade study parameters of weight, cost and product assurance. Author

AEROTHERMODYNAMIC FACTORS GOVERNING THE RESPONSE RATE OF GAS TURBINES

B. D. Madsasc and H. I. H. Saravanamuttoo (Carleton Univ.)

In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 11 p refs (For availability see N75-23575 15-07)

The constraints on gas turbine response rates resulting from serothermodynamic considerations are reviewed and the use of variable geometry to improve the response rate is discussed. Mathematical models, which have to be verified experimentally. permit a detailed investigation of engine transient response. The transient behavior of a single spool unit is quite different from that of a twin spool unit and techniques of improving the response rate of both are discussed; significant gains can be realized and the use of simulation techniques permits these to be evaluated before carrying out actual engine tests.

AN AIRPRAME MANUFACTURER'S REQUIREMENTS FOR

FUTURE PROPULSION CONTROLS

Peter W. Kamber In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 17 p. refs (For availability see N75-23575 15-07)

Selective allocation of service bleed is presented as a means of extending engine life for a mix of nominal and deteriorating engines while preserving a desired thrust distribution. Rating command control is examined as a means to permit simple and definitive power setting, where each power rating is uniquely associated with a pushbutton or throttle position. Hydromechanical and electronic control systems are compared and it is reported that electronics will be used for most advanced control modes. Electronic engine controls are also presented as the foundation for improved coordination with flight controls, and for on-line engine condition manitors.

CONTROL SYSTEM REQUIREMENTS DICTATED BY OPTIMIZATION OF ENGINE OPERATION

Christopher Linley Johnson In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 5 p (For availability see N75-23575 15-07)

A pneumatic mechanical flat rating system is included in the RB 211 control system and the reason for the choice of parameters on which this operates is discussed. On this system the pilot sets up the engine rating and the control then maintains it through variations of temperature and altitude.

N75-23580 Hamilton Standard Div., United Aircraft Corp., Windsor Locks, Conn. Electronic Systems Dept. ENGINE CONTROL FOR HARPOON MISSILE SYSTEM D. A. Prue In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 14 p (For availability see N75-23575

15-07)

The fuel control system for the Teledyne CAE J402-CA-400 angine is described. The control is configured as a low cost, engine mounted, closed loop electronic system. It measures exhaust gas temperature and compressor infet temperature as sensed parameters for acceleration. A unique and straightforward approach to hydraulic system implementation utilizes a direct angine driven centrifugal pump and a proportional solenoid fuel metering system. The pump and fuel metering components constitute one assembly installed in the engine tail cone. The control approach and the reasons for selection of the mode of control and hardware implementation are described. The engine is used as the sustainer propulsion system for the U.S. Navy harpoon missile system. Author

PRAC: A NEW AERO GAS TURBINE ENGINE CONTROL CONCEPT

K. Bauerfeind In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 14 p (For availability see N75-23575 15-07)

The Pressure Ratio Acceleration Control (PRAC) offers a new approach to the control of modern aero gas turbine engines. With the exception of the use of high accuracy pressure transducers mounted in a temperature controlled box directly on the engine all other system components are of today's standard of technology. A simple bread board model of PRAC had been built and successfully tested in conjunction with an Orpheus jet engine in a high altitude test facility. A more sophisticated PRAC control system for a modern supersonic bypass engine is being tested at present in conjunction with an engine simulator and the actual facil system hardware on a control system rig at MTU. The paper outlines the control philosophy of PRAC and presents test results achieved so far.

HELICOPTER ENGINE CONTROL: THE PAST 20 YEARS AND THE NEXT

AND THE NEXT
Edward A. Simonia and Malcolm P. Perks In AGARD Power
Plant Controls for Aero-Gas Turbine Eng. Mar. 1975
(For availability see N75-23575 15-07)

The first 20 years of gas turbine application to helicopters and the progressive evolution of their associated fully automatic engine control systems are surveyed. It is only recently that the dominant performance and safety requirements of the control have emerged with sufficient clarity to allow them to be viewed by an overall systems engineering approach instead of as plecemeat needs. A system is outlined which offers substantial reductions in size and weight over ourrent systems without any saprifice in performance or safety and with marked improvement in integrity. The utilization of digital control techniques leads to simple handling from the cockpit with self monitoring facilities and unambiguous reversionary control modes. Such a system is seen as setting a pattern for control of helicopter engines of the future.

EQUILIBRIUM PERFORMANCE ANALYSIS OF GAS Turbine engines using influence coefficient Techniques

E P. Cockehutt In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 10 p refs (For availability see N75-23575 15-07)

Starting from a specified engine design point, a computer oriented technique is described for establishing the equilibrium off-design performance. The technique involves the control system approach of linearizing the governing equations at the design

point, in order to establish a matrix of engine response influence coefficients. These coefficients are then used to schieve rapid convergence as the cycle iterates to an off-design operating point. For clarity of presentation, the technique is developed for the simple turbojet cycle, but the extrapolation to turbofan cycles is indicated. By way of illustrative example of the equilibrium analysis technique, attention is given to the temporary extraction of large amounts of air bleed from a turbofan, for applications such as flap blowing and reaction controls. Engine response to this perturbation is assessed, and control implications suggested.

GENERALIZED DYNAMIC ENGINE SIMULATION TECH-NIQUES FOR THE DIGITAL COMPUTERS

James Sellers and Fred Teren In AGARD Power Plant Controls for Aero-Ges Yurbine Eng. Mar. 1975 23 p. refs (For availability see N75-2357th 15-07)

Recently advanced simulation techniques have been developed for the digital computer and used as the basis for development of a generalized dynamic engine simulation computer program called DYNGEN. This computer program can analyze the steady state and dynamic performence of many kinds of aircraft gas turbine engines. Without changes to the basic program, DYNGEN can analyze one or two-spool turbofan engines. The user must supply appropriate component performance maps and design point information. Examples are presented to illustrate the capabilities of DYNGEN in the steady state and dynamic modes of operation. The analytical techniques used in DYNGEN are briefly discussed, and its accuracy is compared with a comparable simulation using the hybrid computer. The impact of DYNGEN and similar digital programs on future engine simulation philosophy is also discussed.

N75-23594 National Gas Turbine Establishment, Farnborough (England).

TOTAL POWERPLANT SIMULATION

R V. Cottington /n AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 24 p refs (For availability see N75-23575 15-07)

The capability of predicting the steady state performance of a gas turbine engine is extended to include the prediction of its transient behavior as well. The development and implementation of a total powerplant simulation, consisting of intake and engine, that is capable of predicting both steady state and transient performance are described. The simulation is based on the synthesis of the thermodynamic relationships describing each powerplant component. During the development stage, digital simulation techniques are used, sithough the simulation is finally implemented on a hybrid computer in order to achieve real time operation. Actual steady state and transient test bed results are then used, when available, to validate the simulation.

N75-23595 Lucas Aerospace Ltd., Birmingham (England), USE OF SIMULATION IN THE DESIGN, DEVELOPMENT AND TESTING OF POWER PLANT CONTROL SYSTEMS Stephan Nye and Robert J. Viokera In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar. 1975 13 p (For availability see N75-23575 15-07)

The design, development and testing of an engine control system are discussed. Two specific areas are highlighted: (1) Digital simulation using large scale computers where both engine and control system are represented by mathematical models for evaluation, fessibility and tolerance analysis; and (2) hybrid computers, where a real time digital engine simulation is used in conjunction with a speed controlled rig for real time development of the control hardware.

N76-23596 Lucas Aerospace Ltd., Birmingham (England)
THE USE OF DIGITAL CONTROL FOR COMPLEX POWER
PLANT MANAGEMENT

D. M. Griffiths and R. D. Powell In AGARD Power Plant Controls for Aero-Gas Turbins Eng. Mar. 1975 25 p. refs (For availability see N75-23575 15-07)

The application of digital control techniques to complex power plants is considered by describing the general structure of a digital controller in regard to system requirements. A description is then provided of an engineered controller The characteristics of the unit are given together with details of its construction, software, reliability and integrity targets. From this experience reasonable conclusions can be drawn with respect to its area of application and of the likely future for digital techniques.

TEMPERATURE MEASUREMENT FOR ADVANCED GAS TURBINE CONTROLS

David A. Rohy, T. E. Duffy, and W. A. Compton. In AGARD Power Plant Controls for Aero-Gas. Turbina Eng. Mar. 1975. 27 p. refs (For availability see. N75-23575, 15-07)

Modern gas turbine engines with turbine inlet temperatures higher than metal melting temperatures must have control systems which provide subsecond response to changes in gas or metal temperatures. High quality data are required to provide for the most efficient angine operation consistent with engine safety. Recently developed instruments measure individual blade temperature, and another rion-immersion gas temperature sensor, not yet fully developed, will provide acourate gas temperature data up to 1927 C. These instruments are described with present and potential uses in control systems.

FLUIDIC SENSORS FOR TURSOJET ENGINES

D. Dini and M. Santochi In AGARD Power Plant Controls for Aero-Gas Yurbine Eng. Mar. 1975 28 p. refs (For evallability see N75-23575 15-07)

Fluidics may replace electronics in modern advanced turbojet engine instrumentation technology for comprehensive engine condition monitoring in highly unfavourable environments. This paper discusses some fluidic sensors originally tested in our laboratory: (1) new types of rotational speed sensors utilizing air flows output being a pressure signal proportional to the value to be measured, suitable for analog and digital circuits: and (2) gas stream temperature sensors, using a thermometric bulb, or a bim etaillo spring, or a capillary tube, or a turbulent jet. Corresponding experimental results are summarized and completely fluidic circuits for a small gas turbine and for fire detection in a turbojet engine are described.

A NEW LIGHTWEIGHT FUEL CONTROL SYSTEM FOR ELECTRICAL INPUTS

Heinz Holzein In AGARD Power Plant Controls for Aero-Gas Turbline Eng. Mar 1975 30 p. refs (For availability see N75-23575 15-07)

Most modern control concepts for complex aero gas turbine employ more and more electronic hardware for the function generating part. It was therefore necessary to define the requirements for a simple lightweight fuel metering system, basically consisting of a pumping device, manifolds, filters and an electrically controlled metering value controlled by the electronic box. Such a system has been specified and is being built and developed at present. This fuel system will be used in conjunct in with the PRAC electronic control. The paper describes this system and highlights critical design and development areas.

PUMPING SYSTEM DESIGN RELATED TO FUEL SYSTEM
SPECIFICATIONS

A T Miles In AGARD Power Plant Controls for Aero-Gas Turbine Eng. Mar 1975 32 p (For availability see N75-23576 15-07)

Design of the pump in its context, the fuel system, is discussed System requirements are related to pump limitations. So varied are the requirements that the pumps have to be specifically designed for the system. Discussion first centers on optimizing low pressure systems to minimize heat rejection to the fuel. The concepts of net positive vaccion head and vapor liquid ratio are contrasted in the context of cevitation. Description of two phase flow regimes leads to particular focus on the engine driven backing pump. Design philosophy to cope with contaminated fuel is followed by an analysis of turn down heat to fuel problems as they affect the high pressure dry engine pump and the afterburner pump. The large afterburner turn down flow ratio justifies the vapor core pump design and its principle of operation is outlined.

N78-23601 Colt Industries, Inc., West Hardord, Conn.
ADVANCED ENGINE MOUNTED FUEL PUMP TECHNOLOGY.

John E Cygnor /n AGARD Power Plant Controls for Aero-Gas Turbing Fig. Mar 1975 33 p (For availability see N75-23575 16-07)

Rused upon the flight envelope of a typical high performance sincraft, the relationship between the efficiency of engine

mounted fuel pumps at high fuel flow turndown ratios and the fuel heat sink available to the engine and airframe is discussed. The effect of the pump efficiency on the fuel heat sink is presented in terms of the temperature rise imparted to the fuel by the pump and fuel flow metering system. The sources of losses of conventional fuel pump and metering systems which contribute to the fuel temperature rise are identified and pump and metering systems which will reduce those losses are discussed. Examples of pump types which are applicable to advanced turbine engines are presented in terms of performance parameters and systems. Author Advantages.

JET AND AIRFRAME NOISE

Herbert S. Ribner In AGARD Alteraft Noise Generation, Emission and Reduction Jun. 1975 17 p refs (For availability see N75-30166 21-07)

Basic notions of acoustics [wave equation, plane and spherical waves, sources, dipoles, quadrupoles) are discussed along with an account of jet noise theory, from the dilatation (simple source) point of view, and from the aquivalent quadrupole point of view. The quadrupole sources are shown to dictate a basic directional pattern (self noise and shear noise) which is powerfully modified by convection and refraction effects. The refraction by mean flow velocity gradients is illustrated by laboratory experiments. Jet noise suppression theory examines the role of bypass ratio, the mechanisms of multiple jet shielding, and of reflective shielding by a surface or a gas layer. Airframe noise, distinct from jet noise and other engine noise, is traced to a number of sources on the siroraft. Methods for estimating levels, spectra, and directivity are described.

The fundamental features of sound propagation in lined duots, with and without flow, are reviewed Emphasis is placed on basin physical principles, and simplified results. A set of cherts for direct evaluation of sound attenuation is given Detail predictions necessitate computer analysis based on the basic equations, together with empirical engineering imput on practical duot impedance boundary conditions. The design of lines is discussed, and the engineering trade-offs required in a practical aircraft design solution are reviewed briefly. Author

N75-30173 Environmental Protection Agency Arlington, Va Office of Noise Abatement and Control THE ROLE OF EPA IN REGULATING AIRCRAFT/AIRPORT NOISE

John C Schettino and Harvey J Nozick In AGARD Aircraft Noise Generation, Emission and Reduction, Jun 1975 infs (For availability soo N75-30166-21-07).

A principal finding in the study of aircraft and airport noise in compliance with the Noise Control Act of 1972, was that a comprehensive national program for aircraft/airport noise abatement was needed to insure that the noise control options available to the aircraft manufacturers and operators, the airport operators, the Federal Government, and other public authorities are implemented to protect the public health and welfare. To initiate implementation of this finding and to bring about near term reductions in community noise levels, regulations are proposed for noise abatement flight procedures, noise source emissions (aircraft certification), and airport noise. For the longer turm, a study was conducted to determine the noise reductions required to progressively lower community noise levels resulting from aircraft operations and upon which to base " coordinated long-range aviation noise abatement and control program. The status of EPA regulations and the preliminary results of the long-range aviation noise requirements study are presented.

PROBLEMS IN FAULT DIAGNOSTICS AND PROGNOSTICS FOR ENGINE CONDITION MONITORING

M. Andrenucci and R. Lazzeretti In AGARD Diagnostics and Engine Condition Movitoring, Jun. 1975, 10 p. refs (For evailability) see N75-31083 22-07)

A general discussion of major problems concerning fault detection and isolation in ECM systems is presented. The ECM concept, history and development prospects are reviewed, and various questions regarding instrumentation, sensor requirements and some critical problem areas are considered. A detailed discussion is presented on the concept of an ECM system designed to provide an extensive in-flight diagnostic and prognostic capability. The main characteristics of such a system are analyzed, considering the various aspects of fault logic, parameter selection, diagnostic and prognostic procedures and system operation. Hardware requirements and display techniques are also discussed.

THEORY OF PERIODIC TURBOMACHINE NOISE AND DETERMINATION OF BLADE DAMAGE FROM NOISE SPECTRUM MEASUREMENTS

Dieter Barschdorff In AGARD Diagnostics and Engine Condition Monitoring Jun. 1975 4 p. refs (For availability see N75-31083 22-07)

The mechanical conditions of sotor blades as deduced from vibration or noise spectra measurements are examined. Noise sources and analytical models used to compute periodic noise in the time and frequency domain are discussed. It was noted that irregularities may be observed directly in the time domain using digital averaging techniques. As compared with the Fourier amplitude spectrum of a mechanically perfect rotor stage, additional discrete spectral lines to the blade passing frequency and its harmonics indicate mechanical damage. Moreover, the amplitude distribution of the additional frequency lines can serve as an indication for the specific recurs of the irregularity.

N76-31068 Army Aviation Systems Command, St. Louis, Mo. AUTOMATIC INSPECTION, DIAGNOSTIC AND PROGNOS TIC EYSTEM (AIDAPS): AN AUTOMATIC MAINTENANCE TOOL FOR HELICOPTERS

Thomas C. Beiroso In AGARD Diagnostics and Engine Condition Monitoring Jun, 1975 8 p. refs (For availability see N75-31083

An overall effort to develop an automatic inspection, diagnostic and prognostic system (AIDAPS) for US Army aircraft is summarized. Major parformance requirements of the AIDAPS system include continuous monitoring of critical systems, automatic diagnosis of malfunctions, and prediction of service life remaining in certain components. The objective of this program is to develop, on existing aircraft and angines, AIDAPS systems for ultimate field application on future aircraft such as utility tactical transport aircraft system (UTTAS), heavy lift helicopter (HLH), and advanced attack helicopter (AAH),

TECHNICAL DIAGNOSIS: A SYSTEMS APPROACH
R. J. Brechmen In AGARD Diagnostics and Engine Condition Monitoring Jun. 1975 18 p (For availability see N75-31083 22-07)

The use of computer technology, in a test configuration, to direct tests, make measurements, analyze data, and produce specific output as to the specific nature of a fault in materials or operating systems, is examined. Technical diagnosis is defined and disgnostic systems design is discussed.

N75-31090 Grumman Aerospace Corp., Bethpage, N.Y. ENGINE HEALTH AND FAULT DETECTION MONITORING: ITS FUNCTION AND IMPLEMENTATION PROCEDURE William Brenner In AGARD Diagnostics and Engine Condition Monitoring Jun. 1975 7 p. refs (For availability see N75-31083 22-()7)

The resistic factors relative to an engine health and fault monitoring system and its functions and implementation are discussed as a basis for determining the performance condition and minimum maintenance duties of a high performance aircraft angine. An approach to raise the user's confidence level will be discussed. Opinions will be voiced with reference to whom should be involved in engine health and fault detection monitoring relative to concept formulation and design.

N75-31001 Riv-Officine di Villar Perosa S.p.A., Turin (Italy). A CONTRIBUTION TO THE AERO ENGINES BEARINGS CONDITION MONITORING

S. Brignone, G. Fava, and F. Giordano In AGARD Diagnostics and Engine Condition Monitoring Jun. 1975 20 p refs (For evailability see N75-31083 22-07)

From a survey of the existing techniques used to detect malfunctions in aircraft mainshaft bearings, it is concluded that they are mainly oriented toward the detection of the spailing fatigue initiation. It is pointed out that high speed, low loaded bearings fall mainly from surface distrass caused by roller skidding or deficiencies of the lubrication system and the conclusion is

drawn that a new monitoring device should be developed based on the measure of the beating internal speeds. This device can detect bearing failures, running conditions that might cause an early failure, and could also be used for calculating the bearing accumulated life. Suggestions as to how to make the proposed measurements are given and some experimental data are

AN ADVANCED DIAGNOSTIC ENGINE MONITORING SYSTEM APPROACH

W. R. Krupa and K. R. Hamilton, In AGARD, Diagnostics and Engine Condition Monitoring Jun. 1975 11 p. refs (For availability ses N75-31083 22-07)

The Advanced Diagnostic Engine Monitoring System (ADEMS) is designed to monitor all of the significant engine parameters in-flight, and by the use of onboard digital computational techniques, compare the measured engine condition against normal expected design performance and also against test data related to component performance for a particular power setting. When engine performance degradation is detected, the computer automatically interrogates other engine parameters to indentify and isolate the engine component(s) that are outside normal operating limits. Out of tolerance readings are identified, and the grew is elected to the parameter(s) and component(s) that are outside normal operating limits. Meanwhile, the computer automatically records engine parameters for post-flight analysis and long-term trending. Recording, in this sense, is by exception in order to minimize the amount of post-flight analysis. The expected payoff, when an ADEMS type system is engineered and applied to military aircraft, is a sizable reduction of overall maintenance and operational costs, improved utilization of in-service engines and spare parts, and an in-flight capability to automatically isolate and assess the impact of engine component degradation.

THE NATURE OF PLOW DISTORTIONS CAUSED BY ROTOR
BLADE WAKES

B Lakshminarayana /n AGARD Unsteady Phenomena in Turbomachinery Apr 1978 14 p refs (For availability see N76-25169 16-07) (Grant NsG-3012)

The distortion caused by wakes of rotor blades is one of the least understood phenomena in turbomachinery. An attempt is made to predict the decay characteristics of the defect in axial and tangential velocity components, and the decay of the maximum radial velocity inside the rotor wake using the momentum integral analysis. The predictions agree well with the experimental data taken at the exit of an exial flow fan operating at zero incidence. The measurements are carried out with a three sensor hot wire probe. The wake width is found to grow linearly with distance downstieam and the defect in tangential velocity inside the rotor wake decays fastest of the three components. An empirical expression is also provided for the axial velocity profile of a rotor wake.

EXIT FLOW FROM A TRANSONIC COMPRESSOR ROTOR

William T Thompkins, Jr. and Jack L Kerrebrock In AGARD Unsteady Phenomena in Turbomachinery Apr. 1976. 23 p. refs (For availability see N76-25189. 18-07). IGrant. NGR-22-009-383).

The three dimensional unsteady flow field behind a trensonic compressor rotor with a design pressure ratio of 1.6 at a tip Mach number of 1.2 has been resolved on the blade passing time scale. Quantities determined were total and static prossures. tanpential flow angle, and radial flow angle. The spatial and temporal resolution achieved was sufficient to determine velocity components inside individual blade wakes and in the surrounding flow. From these measurements the flow structure is described at stations immediately behind the rotor and one chord downstream Some dominant features of the flow just behind the rotor are large radial velocity components, large static pressure fluctuations near the blade wakes, and definite unsteadiness (in rotor coordinates) of the wakes. The wake behavior one chord downstream is described in terms of the effect of the strong mean swirl on the behavior of shear disturbances in the outer portion of the annulus, where the mean flow approximates a solid body rotation, a strong, persistent oscillatory flow is found with 16 periods in the circumference as roughly predicted by theory in the inner portion of the annulus the disturbances attenuate axially Author

a straight cascade wind tunnel is used. A rig has been developed, based on linear theory, in order to establish ii wind tunnel where all types of flutter observed in compressors can be investigated in subsonic, transonic and supersonic flow conditions.

N76-25177* Hamilton Standard, Windsor Locks, ConnaPPLICATION OF ROTOR MOUNTED PRESSURE TRANS-DUCERS TO ANALYSIS OF INLET TURBULENCE

Donald B. Hanson. In AGARD. Unsteady Phenomena in Turbomachinery. Apr. 1976. 18 p. refs. (For availability see N76-25189.16-07). (Contract NAS1-12505).

Ministure pressure transducers installed near the leading edge of a fan blade were used to diagnose the non-uniform flow entering a subsonic tip speed turbofan on a static test stand. The pressure response of the blade to the inlet flow variations was plotted in a form which shows the space-time history of disturbances ingested by the rotor. Also, periodically sampled data values were auto- and cross-correlated as if they had been acquired from fixed hot wire anemometers at 150 equally spaced angles around the inlet. With a clean inlet and low wind, evidence of long, narrow turbulence eddles was easily found both in the boundary layer of the fan duct and outside the boundary layer. The role of the boundary layer was to follow and amplify disturbances in the outer flow. These eddles frequently moved around the inlet with a corkscrew motion as they passed through.

ANALYSIS OF UNSTEADY FLOW IN A TRANSONIC COMPRESSOR BY MEANS OF HIGH-RESPONSE PRES-SURE MEASURING TECHNIQUES

H. B. Weyer and H. G. Hungenberg In AGARD Unsteady Phenomena in Turbomachinery Apr. 1976 18 p refs (For availability see N76-25189 16-07)

Experimental investigations on the fluctuating flow inside a transonic axial flow compressor were studied by applying modern pressure measuring techniques, as there are pressure transducers of high natural frequency and accurately reading methods for determining the corresponding time averaged values. Those techniques were used for the examination of the fluctuating wall pressures at the rotor blade tip and of the unsteady total pressures just downstream of the rotor. Some results of these investigations demonstrate the possibilities offered by modern measuring techniques to analyze the unsteady flow in transonic compressors. The flow phenomena at the blade tip sections, as well as the instationary flow behavior downstream of the rotor including the blade wake development, are considered as functions of mass flow rate.

N76-25180 Leicester Univ. (England). Dept. of Engineering MATHEMATICAL MODELLING OF COMPRESSOR STABILITY IN STEADY AND UNSTEADY FLOW CONDITIONS.
A. G. Corbett and R. L. Elder (Cranfield Inst of Tech.) In AGARD Unsteady. Phenomens in Turbomachinery. Apr. 1978. 14 p. refs. (For availability see N76-25169 16-07).

As multistage compressor surge creates an operating limitation for turbolet and turbofan engines, prediction of surge and the effect of parametric changes upon it may be used to improve design. Considered are mathematical models, involving dynamic stage interaction, which can be used to simulate compressor surge under steady and unsteady conditions. Various models were produced based upon the principles of donservation of mass, linear momentum and energy applied to a one dimensional flow using steady state stage characteristics to introduce the effects of the blading. These models are evaluated for their surge prediction capabilities (with steady inlet conditions). It is shown that experimental results may be reproduced quite accurately

THE RESIDENCE OF THE PROPERTY OF THE PROPERTY

using digital simulation techniques and stability criteria applied to impanzed system equations. The most adequate model was used to investigate the response of the model to ramp type and sinusoidal changes in infet total pressure, these typifying non-periodic and periodic variations. The steady state surge line appeared to have little relevance, instantaneous conditions were arising which could not be tolerated in steady conditions Author

N76-25181 Vrije Universiteit, Brussels (Belgium) UNSTEADY CONTRIBUTIONS TO STEADY RADIAL EQUILIERIUM FLOW EQUATIONS

Ch. Hirsch. In AGARD. Unsteady Phenomena in Turbomachinery Apr. 1976 - 12 p. refs (For availability see: N76-25169-16-07)

The contributions to the mendional axisymmetric through flow in small compressors ansing from the unsteady part of the flow are examined. The nonsteady terms occurring in an axisymmetrical radial equilibrium are derived from the general flow equations through an exact averaging process Based on a wake model a theoretical evaluation of these terms is presented and their contribution to the radial distribution of flow functions is discussed on the basis of the inclusion of these terms in a mendional flow calculation program (based on finite elements) With the use of a periodic sampling and averaging techniques. an experimental evaluation of the unsteady contributions is obtained behind a single rotor compressor stage

TURBOFAN COMPRESSOR DYNAMICS DURING AFTER-BURNER TRANSIENTS

Anatole P. Kurkov. In AGARD. Unsteady Phenomena in Turbomachinery Apr 1976 12 p refs (For availability see N76-25169 16-07)

The effects of afterburner light-off and shut-down transients on the compressor stability are investigated. The reported experimental results are based on detailed high response pressure and temperature measurements on the TF30-P-3 turbofan ongine The tests were performed in an altitude test chamber simulating high altitude engine operation. It is shown that during both types of transients, flow breaks down in the forward part of the fan bypass duct. At a sufficiently low engine inlet pressure this resulted in a compressor stall. Complete flow breakdown within the compressor was preceded by a rotating stall. At some locations in the compressor, rotating stall calls initially extended only through part of the blade span. For the shutdown transient the time between first and last detected occurrence of rotating stall is related to the flow Reynolds number. An attempt was made to deduce the number and speed of propagation of rotating stall

THE EFFECT OF CIRCUMPERENTIAL DISTORTION ON FAN PERFORMANCE AT TWO LEVELS OF BLADE LOADING Melvin J. Hartmann and Nelson L. Sanger. In AGARD. Unsteady Phonomena is Turboniachinery 1976 26 p Αpı refs. (For availability see N76-25169 16-07)

Single stage fans designed for two levels of pressure ratio or blade loading were subjected to screen induced circumferential distortions of 90 degree extent Both fan rotors were designed for a blade tip speed of 425 m/sec, blade solidity of 13 and a hub-to-up radius ratio of 0.5. Circumferential measurements of

total pressure, temperature, static pressure, and flow angle were obtained at the hub, mean and tip igdir at five axial stations. Rotor loading level did not appear to have a significant influence on rotor response to distorted flow. Losses in overall pressure ratio due to distortion were most severe in the stator hub region of the more highly loaded stage. At the near stall operating condition tip and hub regions of (either) rotor demonstrated different response characteristics to the distorted flow. No effect of loading was apparent on interactions between rotor and upstream distorted flow fields

N76-26185 Cranfield Inst. of Technology (England) DYNAMIC INTERNAL FLOWS IN COMPRESSORS WITH PRESSURE MALDISTRIBUTED INLET CONDITIONS R E Peacock and J Overli (Norges Tekniske Hoegskole)

Apr 1976 AGARD Unsteady Phenomena in Turbomachinery 14 p. refs (For availability see N76-25169 16-07)

By installing in its intake region a series of distortion screens of various geometries, a low speed lightly loaded compressor was subjected to a range of pressure distortions, broadly classified as square wave and sine wave in the circumferential sense. The effects upon overall performance, rotor normal force coefficient and rotor detailed static pressure distributions was discussed. as well as the cross-coupling effect from the rotor to the distortion Two domains of rotor reaction are isolated, one precipitated by a leading edge promoted perturbation, the other by a trailing edge promoted perturbation. The magnitude of lift or normal force overshoot is found to be a function of a velocity parameter inlated to the time rate of change of blade incidence Author

AXIAL FLOW ROTOR UNSTEADY RESPONSE TO CIRCUM-

FEGENTIAL INFLOW DISTORTIONS
Edger P. Bruce /// AGARD Unsteady Phenomena in Turbornachinery Apr 1978 13 p refs (For availability see N76-25169 16-07)

(Grant Nr.G-3031, Contract N00014-87-A-0228-0005; NR / Proj. 098-038, Proj. SQUID)

The unsteady response of an exial flow fan rotor to steady, circumferential inflow velocity and stagnation pressure distortions is assessed by two different methods These are (1) investigation of the unsteady normal force and pitching inciment on a chordwise element of a rotor blade, and (2) investigation of the variation of the stagnation pressure distortion between the inlet and exit of the rotor Experimental measurements of those unsteady characteristics are presented as a function of the geometry of the rotor -- stagger angle, solidity and steady angle of incidence ·· for sinusoidally varying circumferential distortions with different numbers of distortion cycles. These measurements are compared with several theoretical analyses. While these comparisons indicate some of the deficiencies which exist in the theories, the existence of an unsteady caseade effect and the ability of the theories to adequately predict the trend of the unsteady response due to variations in reduced frequency, rotor stagger angle, solidity and mean incidence angle is clearly demonstrated Author

N76-25187 Rolls-Royce Ltd., Derby (England) Engine Div THE RELATIONSHIP BETWEEN STEADY AND UNSTEADY SPECIAL DISTORTION

C. Freeman In AGARD Unsteady Phenomena in Turbomachinary Apr. 1976 16 p. refs (For availability see N76 25169 16-07)

Simple theories of turbulence are used to develop a model that relates the fluctuating spacial distortion to the time average spacial distortion. This model uses the relationship between the fluctuating total pressure, the fluctuating velocities, the Reynolds stress and the mean velocity gradient. These fluctuating total pressures are then used with a correlation coefficient to determine the amplitude of the fluctuating average total pressure over part of the compressor face. Comparison: are made between the method and experiment to show that the method deporibes many features of the flow Author

N75-25108 Cincinnati Univ., Ohio TRANSMISSION OF CIRCUMFERENTIAL INLET DISTOR-TION THROUGH A HOTOR

W R Wells, W Tabakoff, and C. J Savell (GE Co., Cincinnati, Ohio) In AGARD Unsteady Phonomena in Turbomachinery Apr. 1976 10 p. refs (For availability see N76-25169 16-07)

Analytical methods of predicting the propagation of stationary circumferential distortion patterns through a rotor are presented The analysis considers the effects of finite blade chord length and Mach number on the transmission by a semi actuator disc theory in addition, a more basic theory using the method of distributed singularities with thin airfoils is discussed to account for the effect of finite solidity on the distortion transmission. This thin airfoil theory is limited to the case of no steady loading on the rotor. The results of the analytical analysis is compared with existing experimental results.

N76-26189 Pract and Whitney Aircraft, East Hartford, Conn MULTIPLE SEGMENT PARALLEL COMPRESSOR MODEL FOR CIRCUMFERENTIAL FLOW DISTORTION

Robert S Mazzawy III AGARD Unsteady Phenomena in Turbomachinery Apr 1976 14 p refs [For availability see N76:25169 18:07]

A compressible nonlinear model for prediction of the flow field of a circumferentially distorted compressor has been developed by using multiple parallel segments and by accounting for deviations from undistorted compressor performance. The model is applicable to large amplitude inlet circumferential distortions of total pressure and/or temperature, as well as circumferential variations of exit static pressure, with the restriction that the circumferential extent of the distortion is large relative to circumferential blade spacing. The distorted compressor stability criterion is based upon the limit of static pressure rise capability for a single distorted flow segment. This model requires the undistorted performance characteristics for each blade row; however, a modified version based upon the overall compressor performance gives an accurate approximation when detailed blade row characteristics are not evaluable.

THE EFFECT OF TURBULENT MIXING ON THE DECAY OF SINUSCIDAL INLET DISTORTIONS IN AXIAL FLOW COMPRESSORS

H. Mokelko In AGARD Unsteady Phenomena in Turbomschinery Apr. 1976 30 p. refs (For availability see N76-26169 16-07) A small perturbation actuator disc theory is presented for

the prediction of the decoy of sinusoidal flow distortions in high hub tip ratio exist compressors with steady, droumferential inlet makinstribution. The theory accounts for the turbulent mixing of the flow upstream and within the compressor. Decay rates and dircumferential phase shifts of first, second, fourth and eighth order cosine wave pressure and velocity perturbations are calculated for equal amplitudes and phases of the four total pressure disturbances upstream of the compressor. The results are compared with interstage traverse data obtained from a 4-stage sxial flow compressor. A comparison between corresponding analytical results obtained from the same theory neglecting viscosity and the experimental data is also performed. It is found that turbulent mixing has little influence on the development of the first order disturbance but that the influence grows repidly as the order of the disturbance increases.

Uwe W. Schaub. In AGARD. Unsteady Phenomena in Turbomachinery. Apr. 1976. 14 p. refs (For availability see N76-25169-16-07).

During trensition maneuvers from lan supported to wing supported flight VTOL litting fairs routinely encounter extremely large spetial crossflow distortions. The variation in fair performance and the character of the flow distortions responsible for this variation were explored experimentally and on the basic of a simple analytical model of a lifting fair. The inflow and exit plans distortions in this model were generated by potential flow models, and the fair through flow was calculated on the basis of an arbitrary number of discrete circumferential fan segments. The lifting fair performance was predicted and compared with experiments over a wide range of transition conditions, and it is shown that while the crossflow causes large circumferential nonuniformities, the overall performance becomes seriously dagraded only at large crossflows and large fan speeds. refs (For availability see N78-25169 18-07)

The unsteady boundary layer due to a gust propagating pest an isolated airfoil and on airfoils in cascade was measured with a hot wire anemometer in a low speed gust tunnel. Coherent signals were obtained by a phase lock averaging technique that was implemented in an on-line analysis using a PDP 12 computer. Changes in a boundary layer shape factor, noise level, and pressure gradient were correlated over a complete gust cycle. It is concluded that the character of the boundary layer changes from laminer to turbulent and back to laminar during the course of a gust occur and the course of the propagations. These measurements help explain certain promalies that were observed during a previous study of the prossure fluctuations due to gust loadings on airfoils and cascades.

A CABCADE IN UNSTEADY FLOW

Francis R Ostdiek In AGARD Unsteady Phenomena in Turbomachinery Apr. 1976 13 p. rafs (For availability see N76-25169 16-07)

A low speed atmospheric inlet cascade wind tunnel was constructed to obtain a flow which has a sinusoidal variation in flow direction. A stationary five blade cascade was held in a 7.62 x 25.4 cm test section. The wind (unnel inlet, which included guide venus, was furced to oscillate by a motor driven clark about an exis transverse to the cascato. The venus guided the flow along the instantaneous axis of the inite and, thus, achieved a variable flow direction of any prescribed frequency in the 0 to 18 Hz range while the flow magnitude was nearly constant. Each surface of the center sirfoll contained ten static pressure parts. The pressure fluctuations over most of both surfaces were near sinuscidal and the cyclic average showed little depandance on frequency or valouity. The pressure fluctuations decreased in amplitude along the shord on the pressure surface and changed phase on the suction surface near mid-chord The prossures on both surfaces were adjusted by slow moving waves and showed only a small change in phase angle with increased frequency. The unsteady pressure profiles are in excellent agreement with theory near the leading edge Author

THE UNSTEADY AERODYNAMIC RESPONSE OF AN AIRFOIL GASCADE TO A TIME-VARIANT SUPERSONIC INLET FLOW FIELD

Senford Fleeter, Allen S. Novick, and Ronald E. Riffel. In AGARD Unstoady. Phenomena in Turbomachinery. Apr. 1976. 14 p. refs. (For availability see N76-25169-16-07). (Conttaut F44620-74-C-0065).

The time dependent serodynamic cascade phenomena related to the unsteady pressure disturbance and varying incidence in the cascade entrence flow field were investigated over a cancade inlet Mach number range of 153 to 163 with cascade static pressure ratios of 155 to 147. The range of the reduced frequency varied from approximately 0.03 to 0.12. The dynamic data obtained is presented in the form of the amplitude of the unsteady pressure and its phase as referenced to the sidewall transducer immediately downarream of the oscillating wedge. This data demonstrated the effect of the raduced frequency, cascade static pressure ratio, and the cascade inlet Mach number on the time variant pressure as measured on the sidewall in the cascade entrance flow field and on the pressure and suction surfaces of one of the cascaded advanced design transonle sirfolis.

W. R. Chadwick, J. K. Bell, and M. F. Platzer (Naval Postgraduate School) In AGARD Unsteady Phenomena in Furbomachinery Apr. 1976 13 p. refs (For availability see N76-25169 16-07)

Supersonic flow past oscillating finite cascades with subsonic leading edge locus is analyzed by solving the nonlinear transonic small perturbation equation. Jsing the properly approximated Ranking-Hugoniot equations for the oscillating head shocks and continuing by the method of characteristics the entrance flow field into the cascade is computed and the influence of blade thickness on the aerodynamic pressure distributions is determined For the single oscillating wedge the solution is in good agreement with Carrier's exact solution and it is found that single blades exhibit a pronounced effect of blade thickness throughout the lower frequency range, which appears to be alleviated by cascading. For zero blade thickness, the linearized characteristics theory is recovered. Sample calculations with this theory for complete cascade configurations are in excellent agreement with recent results indicating the possibility of supersonic torsional cascade flutter over a wide range of parameters.

PRELIMINARY RESULTS FOR SINGLE AIRFOIL RESPONSE TO LARGE NONPOTENTIAL FLOW DISTURBANCES P. V. K. Parumal and F. Sisto. In AGARD. Unsteady Phenomena

in Turbomachinery Apr. 1976 17 p refs (For availability see N76-25169 16-07)

(Contract N00014-87-A-0202-0016; NR Proj. 094-393)

The unsteady response of a flat plate airfoil to large nonpotential flow disturbances in the form of a translating rectangular grid of eddy array is evaluated. A suitable stream function to represent the translating nonpotential vortex array is chosen. The problem is solved in two stages, namely, auxiliary solution and time marching solution. By auxiliary solution is meant the solution of the problem which completely neglects the presence of the wake vortex sheet and treats time as a parameter; this results in a steady flow type of analysis. The time marching part of the analysis increments time by equal steps starting from zero time, makes use of the auxiliary solution, keeps track of the shedding and growth of the wake vortex sheet, evaluates the unsteady response, and continues along with time axis up to any specified maximum time limit. Preliminary numerical results from a computer program are presented

THE PASSAGE OF A DISTORTED VELOCITY FIELD THROUGH A CASCADE OF AIRFOILS

John J. Adamczyk In AGARD Unsteady Phenomena in Turbomachinery Apr. 1976 11 p refs (For availability see N76-25189 16-07)

An analysis has been developed to predict the unsteady force and moment generated by the passage of a timewise periodic total pressure distortion through an arbitrary cascade of airfoils The mathematical formulation of this analysis is based on the assumption that the magnitudes of the timewise fluctuations of the variables which describe the flow field are small compared to their time average values. This assumption permits the development of a linear unsteady perturbation analysis about a steady flow field. In addition to this linearization assumption the fluid medium is assumed to be incompressible and inviscid. The mathematical development begins by decomposing the velocity field surrounding an infinite cascade of airfolls into its irrotational and rotational components. The rotational component is associated with an upstream unsteady total pressure distortion and is defined in terms of the vorticity field associated with the distortion pattern The irrotational component is further decomposed into a steady and unsteady part. A combined analytical and numerical procedure has been developed to solve the field equations which govern the rotational and irrotational velocity fields. Results of this analysis show a strong influence of mean loading on the unsteady force generated by the passage of a one dimensional gust through a cascade of compressor blades

AN ON-ROTOR (NYESTIGATION OF ROTATING STALL IN

AN AXIAL-FLOW COMPRESSOR

M. R. Sexton, W. F. OBrien, Jr., and H. L. Moses In AGARD

Unsteady Phenomena in Turbomachinery Apr. 1976 refs (For availability see N76-25169 16-07) (Contract N00014-67-A-0226-0005; NR Proj. 098-038)

Rotating stall is an unsteady phenomenon in axial flow compressors involving rapid pressure changes and lift variations on the rotating blades of the compressor. Measurements of the surface pressures on the rotor blade provide information to study the variation of lift of the rotating blade, and to improve the general understanding of rotating stall. Such on-rotor measurements require special pressure transducers, mounting techniques and data transmission systems. A multichannel radio telemetry system was used in this investigation to transmit simultaneous pressure measurements from up to six transducers mounted on e rotating blade. Measurements were made on both the pressure and suction sides of the blade, at different span locations. Results include rotor blade surface pressure measurements for compressor flow rates up to and including stell. Pressure variations during the dynamic stall event were used to determine the lift time variations on the blade.

DETAILED FLOW MEASUREMENTS DURING DEEP STALL IN AXIAL FLOW COMPRESSORS

Ivor J. Day In AGARD Unsteady Phenomena in Turboniachinery

Apr. 1976 10 p refs (For availability see N76-25169 16-07)
Detailed measurements have been obtained for the flow in a stalled three stage compressor of high hub tip ratio which is operating deep in the rotating stall regime. Using high frequency transducers and a conditional sampling procedure made it possible to obtain information on the detailed structure of the stall cells and to prepare an overall picture of the flow field in the compressor. The results of the measurements show some new features which are at variance with conventional ideas about stall cells. Author

AIRCRAFT GAS TURBINE CYCLE PROGRAMS: REQUIRE-MENTS FOR COMPRESSOR AND TURBINE PERFORM-ANCE PREDICTION

K. Bauerfeind In AGARD Mod. Prediction Methods for Turbomachine Performance Jun. 1976 12 p (For availability see N76-26208 17-07)

Typical design applications for an engine performance program are shown. A characteristic structure is presented of a thermodynamic engine model for steady state performance prediction. A technique for determining nondimensional engine performance is derived from non-dimensional component performance Compressor and turbine characteristics are also discussed A.S.K.

N76-26210 lows State Univ. of Science and Technology, Ames. COMPRESSOR AND TURBINE PERFORMANCE PREDICTION SYSTEM DEVELOPMENT: LESSONS FROM THIRTY YEARS OF HISTORY

George K. Serovy In AGARD Mod. Prediction Methods for Turbomachine Performance Jun 1976 19 p refs (For availability see N76-26208 17-07)

Methods are reviewed for prediction of aerodynamic performance of aircraft propulsion system turbomachinery configurations. Progress is traced in the two classes of methods which can predict only overall performance characteristics or maps. These methods were conceived at least thirty years ago and are not only used, but continue to be the subject of research today. Prediction methods which include flow field definition in the blade passages of compressors and turbines are described.

DESIGN OPTIMIZATION AND PERFORMANCE MAP PREDICTION FOR CENTRIFUGAL COMPRESSORS AND RADIAL INFLOW TURBINES

David Japikse In AGARD Mod Prediction Methods for Turbomachine Performance Jun. 1976 15 p refs (For availability see N76-26208 17-07)

The initial specification of compressor and turbine geometry and performance characteristics, including operating maps, can follow different paths depending on the degree of departure from previous design experience. Principal attention is focused on totally new design problems requiring systematic design optimization to meet performance criteria under diverse operating conditions. The fundamental flow physics involved for both the centrifugal compressor and radial inflow turbine are briefly reviewed with principal attention focused on the strategy used for selecting optimum stage configurations. The performance map is obtained from the final step of this design optimization exercise.

CHARACTERIZATION OF COMPONENTS PERFORMANCE AND OPTIMIZATION OF MATCHING IN JET-ENGINE DEVELOPMENT

Alain G. Habrard In AGARD Mod. Prediction Methods for Turbomachine Performanca Jun. 1976, 19 p. refs (For availability see N76-26208 17-07)

Design and development of jet-engines require prediction and later, characterization through test analysis, of the performance of the engine and its components. Knowledge of component characteristics is generally synthesized in mathematical models which contribute highly to efficient design and development. At the beginning of development (i.e. before first runs of prototype engines) models are essentially based on estimates and rig test results. Problems are then encountered when engine test results are compared to prediction. Methods using engine test analysis to identify component operating characteristics as installed in the engine and leading to models more representative of aerothermodynamic behavior of engines, are presented. Such models appear to be very useful tools during the various phases of development. Application and coordination with tests are discussed and particularly relative matching of components and control schedules optimization.

N74-25551 Lockheed-California Co., Burbank. EFFECT OF YAW DAMPER ON LATERAL GUST LOADS IN DESIGN OF THE L-1011 TRANSPORT

Frederick M. Hobilt In AGARD Active Control Systems for Load Alleviation, Flutter Suppression and Ride Control Mar. 1974 p 1-10 refs (For availability see N74-25550 15-02)

In the design of the L-1011 transport, the reduction lateral gust loads, in continuous turbulence, due to the presence of a yaw damper was reflected in the limit design loads. The resulting load reduction was about 27 percent. In establishing the limit design loads, both the mission analysis and design envelope forms of continuous turbulence gust loads criteria were used. Account was taken, under both forms of criteria, of the fraction of time the damper might be inoperative. The effect of saturation of the damper at the limit-load level was also taken into account. This effect was determined by means of time-history analyses in which the input was a random gust velocity and the rudder angle limits (governed by available hinge moment) were included

Alleviation, Flutter Suppression and Ride Control Mar. 1974 p 11-22 refs (For availability see N74-25550 15-02)

The design criteria for fixed wing aircraft are considered in relation to the active control systems. The reduction of static design loads, engine failure and surge loads, gust loads, and fatigue design loads are discussed along with the improvement of flutter characteristics

N74-25553* National Aeronautics and Space Administration. Langley Research Center, Langley Station, Va STATUS OF TWO STUDIES ON ACTIVE CONTROL OF AEROELASTIC RESPONSE AT NASA LANGLEY RESEARCH

CENTER

Irving Abel and M. C. Sandford. In AGARD. Active Control Systems for Load Alleviation, Flutter Suppression and Ride Control Mar. 1974 p 23-48 refs (For availability see N74-25550 15-02) CSCL 01B

The application of active control technology to the suppression of flutter was successfully demonstrated during two recent studies in the Langley transonic dynamics tunnel. The first study involved the implementation of an aerodynamic-energy criterion, using both leading- and trailing-edge controls, to suppress flutter of a simplified delta-wing model. Use of this technique resulted in an increase in the flutter dynamic pressure of approximately 12 percent for this model at a Mach number of 0.9. Analytical methods used to predict the open- and closed-loop behavior of the model are also discussed. The second study, which is a joint effort with the Air Force Flight Dynamics Laboratory, was conducted to establish the effect of active flutter suppression on a model of the Boeing B-52 Configured Vehicle (CCV). Some preliminary results of this study indicate significant improvements in the damping associated with the critical flutter mode. Author

ACTIVE FLUTTER SUPPRESSION ON WINGS WITH EXTERNAL STORES

G. Haidi, A. Lotze, and O. Sensburg. In AGARD. Active Control Systems for Load Alleviation, Flutter Suppression and Ride Control Mar 1974 p 57-76 refs (For availability see N74-25560 15-02)

A control system is described, which is able to suppress flutter of wing-external store combinations. The serodynamic flutter suppression forces are generated by movable vanes, attached to the stores, which are moved by a feedback signal from the store motion in such a way, that these forces damp the store motion. By adjusting the phase of the servoloop it is possible to have an active flutter-system below the flutter-speed of the passive system. This arrangement can be used to excite the flutter-mode at subcritical speeds. By switching off the servoloop, damping and frequency can be evaluated. The active flutter suppression system can also be used for reducing the level of externally forced vibration on stores which could occur through excitation by buffet or gusts. Tests results for an elastic wind-tunnel model are given and compared with analytical predictions. Correlation is very good, considering the complexity of the problem.

THE TREATMENT OF INTERACTION OF HANDLING QUALITIES, STABILITY, AND CONTROL ON STRUCTURAL LOADS BY CURRENT SPECIFICATIONS Summary Report Clifford F. Newberry (Boeing Co., Wichita, Kans.) Jun. 1974 15 p refs

(AGARD-R-621) Avail: NTIS HC \$4.00

Aircraft structural loads arise not only from such sources as mansuvers, landings, gusts and taxling, but are developed and influenced by aircraft handling qualities, stability and control characteristics. The reacture, the aerodynamics, and the control system are jointly considered to evaluate the capability to solve the interaction problem. Usage and adequacy of existing specifications are considered. Factors which influence the decision to use advanced control techniques and analytical studies and tests to insure technical integrity are explored. Author

ADVANCES IN CONTROL SYSTEMS

May 1974 313 p refs in ENGLISH partly in FRENCH Conf. Presented at 17th Meeting of the Guidance and Control Panel of AGARD, Gello, Norway, 24-26 Sep. 1973 (AGARD-CP-137) Avail: NTIS HC \$18.75
The proceedings of a conference on control systems for aircraft

control, engine control, and automatic pilots are presented. The subjects discussed include the following: (1) applied control theory, (2) control system performance optimization, (3) control system architecture and reliability, (4) application of advanced control systems, and (5) integrated flight control and operations. The characteristics of control systems for specific types of aircraft are analyzed. The development and application of fly by vire techniques are reported. The use of computers as an aid to flight control system design is explained. For individual titles, see N74-31430 through N74-31457.

N74-31430 Systems Technology, Inc., Hawthorne, Calif. A HISTORICAL PERSPECTIVE FOR ADVANCES IN FLIGHT CONTROL SYSTEMS

Duane McRuer and Dunsten Greham In AGARD Advan in Control Systems May 1974 7 p refs (For availability see N74-31429 21-02)

VALUE

A brief history of the investigations into the nature of aircraft control and stability is presented. The activities of early investigators are examined and some of their accomplishments are cited. The historical eras are divided into the periods of 1890 to 1934, 1934 to 1947, and 1947 to the present. Examples of stability developments for specific aircraft are cited.

THE DIGITAL AIRPLANE AND OPTIMAL AIRCRAFT GUIDANCE

Allen D Dayton In AGARD Advan in Control Systems May 1974 14 p. refs (For availability see N74-31429 21-02)

The use of optimal flight path guidance for aircraft in satisfying various military and civilian mission requirements is discussed. The concepts, systems, and algorithms which make optimal aircraft flight path guidance feasible are presented. The digital airplane which is based on a large digital computation capability, a digital data bus, sensors, and display systems is used as an example. The development of the methodology and algorithms for directing the aircraft is investigated. Author

N74-31432 Norges Tekniske Hoegskole, Trondheim. Some integrity problems in optimal control Systems

Ole A. Solheim In AGARD Advan. in Control Systems May 1974 10 p. refs (For availability see N74-31429 21-02)

A multivariable feedback control system is defined as being of high integrity if it remains stable under failure conditions. Integrity problems encountered in optimal control systems are investigated. Two types of failure conditions are considered, namely actuator failure and sensor failure. As to the structure of the control system, a linear feedback law with feedback from all the state variables is considered. Systems with state estimators are also dealt with. The integrity problem is discussed based on the eigenvalues of the closed-loop system. Some design procedures are suggested. Finally, some numerical results are presented.

APPLICATION OF MODAL CONTROL THEORY TO THE DESIGN OF DIGITAL FLIGHT CONTROL SYSTEMS Ulrich Hartmann /n AGARD Advan. In Control Systems May 1974 21 p. refs (For availability see N74-31429 21-02)

The design of digital flight control systems is substantially simplified by using model design methods. The theory of mode design is based on a state space description of the control system. For a desired pole distribution of the control system this theory directly provides a gain matrix for the feedback of the state variables. Due to the fact that all state variables are not always available, the problem of estimating non-measurable state variables arises. For solving this problem the theory of observers can be used. It shows however that an observer is not in a position to provide without adaptation usable estimated values of the missing state variables for the complete flight range. For solving practical design problems a minimum order observer is therefore particularly suitable as it is generally easier to obtain programmable approximation laws for the small number of parameters of this observer. It was further attempted to circumvent the estimation problem by the following means: (1) simplification of the state equations to eliminate non-measurable state variables, (2) transformation of the state vector and, (3) appropriate selection of the desired pole distribution. It showed that in this way a prompt and direct design of discrete-time flight control systems is possible. Two examples are used to demonstrate the results of simulations and flight tests: The design of a pitch attitude control system and a roll/yaw control system for a STOL aircraft.

N74-31434* National Aeronautics and Space Administration. Langley Research Center, Langley Station, Vs. COMPUTER-AIDED DESIGN OF CONTROL SYSTEMS TO MEET MANY REQUIREMENTS

A. A. Sohy, W. M. Adams, Jr., and K. G. Johnson In AGARD Advan in Control Systems May 1974 7 p refs (For availability see N74-31428 21-02) CSCL 01C

A method is described for using nonlinear programing in the computer-aided design of airplane control systems. It is assumed that the quality of such systems depends on many criteria. These criteria are included in the constraints vector (instead of attempting to combine them into a single scalar criterion, as is usually done), and the design proceeds through a sequence of nonlinear programing solutions in which the designer varies the specification of sets of requirements levels. The method is applied to design of a lateral stability augmentation system (SAS) for a fighter airplane, in which the requirements vector is chosen from the official handling qualities specifications. Results are shown for several simple SAS configurations designed to obtain desirable handling qualities over all design flight conditions with minimum feedback gains. The choice of the final design for each case is not unique but depends on the designer's decision as to which achievable set of requirements levels represents the best for that system. Results indicate that it may be possible to design constant parameter SAS which can satisfy the most stringent handling qualities requirements for fighter simplenes in all flight conditions. The role of the designer as a decision maker. interacting with the computer program, is discussed. Advantages of this type of designer-computer interaction are emphasized. Desirable extensions of the method are indicated.

A DESIGN PROCEDURE UTILIZING CROSSFEEDS FOR COUPLED MULTILOOP SYSTEMS

Paul S. Basile and R. E. Curry (MIT, Cambridge) In AGARD Advan, in Control Systems May 1974 10 p refs (For availability see N74-31429 21-02)

A frequency-domain design procedure for decoupling multiinput, multi-output systems is described; the frequency domain
has the advantage of providing insight and ease of satisfying
specifications that are difficult to meet with state-space methods.
A design procedure for a two-input, two-output system without
crossfeeds is presented first; crossfeeds are then introduced to
after the open loop dynamics, and the design procedure is applied
to the modified plant. The constraints on the choice of crossfeeds
are discussed. Extension to a two-input, three-output system is
made when one of the outputs is dominated by enother; guidelines
for uhoosing the crossfeeds are given. This procedure is applied
to design a lateral cruise control system for the space shuttle
orbiter exact decoupling with crossfeeds results in excellent closed
loop response.

N74-31436 Norwegian Defence Research Establishment, Kjeller Div. for Electronics. CONSTRUCTION OF SUBOPTIMAL KALMAN FILTERS BY PATYERN SEARCH

Nils Christophersen and Truls Lange-Nielsen In AGARD Advan. In Control Systems May 1974 6 p refs (For availability see N74-31429 21-02)

A systematic method for the optimal determination of parameters in suboptimal Kalman filters is presented. Such simplified filters are frequently necessary in order to implement a Kalman filter on a small special purpose computer. In order to optimize the performance of these filters, a parameter optimization problem may be involved. The method of solution is a modified version of Rosenbrock's pattern search. This is a direct search, permitting a very wide class of performance measures not indessarily analytical in nature. The example given is the determination of a suboptimal filter for a hybrid marine navigation system with thirty state variables.

USE OF ADVANCED CONTROL THEORY AS A DESIGN
TOOL FOR VEHICLE GUIDANCE AND CONTROL
P. M. Brodle In AGARD Advan in Control Systems May
1974 10 p (For availability see N74-31429 21-02)

(Contract F08635-71-C-0227)

A technique is demonstrated which permits the numerical solution of the linear optimal regulator problem to be used as a generalized design tool. In particular this technique affords simplification over the usual frequency domain methods for high order guidance and control systems while retaining compatibility with the frequency domain especially for stability analysis. In addition to making a more rapid solution to the design problem possible, the structure of the optimal controller lends itself to the combination of the guidance and control problems into a single optimum or best solution.

UNSPECIFIED TERMINATION TIMES

N74-31438 Norges Tekniske Hoegskole, Trondheim.
OPTIMAL CONTROL OF STOCHASTIC SYSTEMS WITH

Rolf Henriksen In AGARD Advan in Control Systems May 1974 10 p. refs (For availability see N74-31429 21-02)

A game-theoretic approach to optimal control problems of discrete-time stochastic systems with unspecified termination times is presented. In somewhat the same sense as stochastic systems with fixed termination times may be regarded as a kind of single-experiment (fixed samplesize) games, stochastic systems with unspecified termination times may be regarded as a kind of sequential games. A major part of the paper is devoted to the synthesis of Bayes control policies for truncated control processes, a term which is quite analogous to truncated sequential games. Two simple examples are given.

F.15 EAGLE FLIGHT CONTROL SYSTEM

Edward H. McDonald In AGARD Advan. In Control Systems May 1974 8 p (For svallability see N74-31429 21-02)

The high performance demands of the flight control systems of today's fightur type aircraft normally are associated with undesirable complexity. How this complexity was minimized, the hardware solution to historical design problems, and how the solution evolved are discussed. A narration includes the prehardware design phase during which time exhaustive simulation analyses were made. The unique integration of flight controls with other sircraft systems is revealed along with limited performance and test results. The more significant subcomponents/systems are separately addressed in amely the automatic flight control system, the stabiliator actuator, and the control stok boost and pitch compensator package. In conclusion, overall salient capabilities are enumerated which substantistes the existing high confidence level relative to the system.

A sight line autopilot (SLAP) was designed for the AC-130 Gunship to improve the gun pointing ability. This paper presents the unique design procedure and development philosophy that was used. It emphasizes the peculiarities of this weapon delivery concept, the problem areas and the results of the design Multi-axes coupling, digital computer control, available measurements, and optimistic performance requirements prompted the use of modern control design techniques. Optimal control laws were generated for all modes and submodes. No classical analysis was performed. Proportional-plus-integral control was included to reduce nonlinear effects. Both linear and nonlinear simulation results verified that the sutopilot met the optimistic performance requirements in spite of poor performing serve-actuators, which limited the bendwidth of control laws. More recently, ground and flight tests have been performed.

AN EXPERIMENTAL INVESTIGATION INTO DUPLEX

DIGITAL CONTROL OF AN ENGINE WITH REHEAT
J. F. O. Evans and K. A. Heips In its Advan. in Control Systems
May 1974 14 p (For availability see N74-31429 21-02)

The application of cross-monitoring computers with a hydromechanical back-up system to control a P.S. 50 jet engine is discussed. The choice of a digital control system was based on the complexity of modern engine control requirements especially at the reheat end of the system. Total hydromechanical control without the computer results in complexity and increased costs. The digital system is well suited to the function of scheduling, decision making, time-varying parameters, and nonlinearity conditions. The features of the digital equipment in high integrity systems are analyzed. The basic control system and the reversionary mode of the system are examined. The results of performance tests using the computer controlled system are reported.

(West Germany): REALIZATION AND FLIGHT TESTS OF AN INTEGRATED DIGITAL FLIGHT CONTROL SYSTEM

Robert K. Zach. In AGARD. Advan. in Control Systems. May 1974. 20 p. refs (For availability see: N74-31429-21-02).

The introduction of digital computers into modern aircraft control systems for the integration of all the functions in a complex automatic flight control system is discussed in order to restize such practical systems economically, the functional requirements for the computer and interface were first derived by the analysis of the tasks and by the hybrid simulation of the functions, where the aircraft and actuators were simulated on an analog computer and the AFCS on a general purpose digital computer. Based on these requirements, a free programmable in-flight simulator was designed, built and flown in the test alreraft. This equipment is compatible with the laboratory hybrid elmulation equipment. The in-flight simulator allows experiments of different control laws, and was used to check and prove the required control form for a special digital system developed for flight control. As is shown, this latter system fulfills all the functional requirements and consists of a small digital computer, an interface for signal conversion and a pilots control panel. All functions of a modern AFCS, such as stabilizer, automatic approach, automatic landing and other autopilot functions as well as preflight and inflight tests were integrated, by programming the semiconductor mermory. The flight trials of this system in the test sircraft showed the satisfactory functioning of the system over the whole aircraft flight envelope. The good control characteristics were confirmed with the measured responses in flight.

N74-21448 LTV Aerospace Corp., Dallas, Tex. Systems Div. APPLICATION OF DIGITAL FLY-BY-WIRE TO FIGHTER/ATTACK AIRCRAFT

Ryland A. Baldwin In AGARD Advan, in Control Systems May 1974 10 p refs (For availability see N74-31429 21-02)

Some of the benefits to be derived from digital fly-by-wire flight control systems applied to atrack/fighter aircraft are presented. An integrated stability augmentation system and control augmentation system mechanization is described. Design criteria are reviewed and trade studies that were made to establish the proper level of redundancy are described. The resulting quadruplex system configuration is presented showing interfaces with digital processors. Computer studies undertaken to support selection of the proper digital word length and iteration rate are summarized. and the effect of variations of these parameters upon system performance is shown. A brief description of the data handling system and the computer requirements are included along with a block diagram summarizing the integrated system. Performance of the digital flight control system is compared to that of the analog system now in use in the A-7 siroraft. Open loop test data of a laboratory test configuration in which aircraft control laws are programmed are given.

08 AIRCRAFT STABILITY AND CONTROL

A digital fly-by-wire flight control system was designed, built, and for the first time flown in an airplane. The system, which uses components from the Apollo guidence system, is installed in an F-8 airplane as the primary control system. A lunar module guidence computer is the central element in the three-axis, single-channel, multimode, digital control system. A triplex electrical analog system which provides unaugmented control of the airplane is the only backup to the digital system. Flight results showed highly successful system operation, although the trim update rate was inadequate for precise trim changes, causing minor concern. The use of a digital system to implement conventional control laws proved to be practical for flight. Logic functions coded as an integral part of the control laws were found to be advantageous. Although software verification required extensive effort, confidence in the software verification required

N74-31451 Deutsche Forschungs- und Versuchsansteit füer Luft- und Raumfahrt, Brunswick (West Germany). DIGITAL FLY-EY-WIRE CONTROL SYSTEM WITH SELF-DIAGNOBING FAILURE DETECTION R. Onken, H. P. Joenck, L. Tacke, and M. Gottschlich In AGARD

R. Onken, H. P. Joenck, L. Tacke, and M. Gottschlich /n AGARD Advan_in Control Systems May 1974 7 p. refs (for evallability

see N74-31429 21-02)

A solution is presented to the problem of achieving real fail-safe behaviour for fly-by-wire systems, no longer depending on the reliability of the monitor/voter device and the probability of the occurrence of dorment errors. This is accomplished by the use of stand-by redundancy in conjunction with selfdisgnosing failure detection which is independent of the control signal state. Each redundant unit is autonomous with respect to the failure detection, such that, depending on the inspection rate, perfect information about the reliability status of the system, including the failure detection itself, is available at any time. The feasibility of this approach is demonstrated by the fly-by-wire system which is installed and successfully flown in a HFS 320 jet aircraft.

FLIGHT EXPERIENCE WITH AN EXPERIMENTAL ELECTRICAL PITCH-RAYE-COMMAND/ATTITUDE-HOLD FLIGHT
CONTROL SYSTEM

H. A. Mooij In AGARD Advan. in Control Systems May 1974 8 p. refs (For availability see N74-31429 21-02)

The introduction of electrical primary flight control systems makes studies in many aspects of their application highly desirable. One important aspect is the development of handling qualities criteria as a guide for system design. To this and an experimental pitch-rate-command/attitude-hold flight control system installed in a Beechcraft Queen Air-80 was used in two flight research programs. Results of these programs are discussed in this paper. The first program is related to pilot workload reduction for the safe execution of two-segment noise-abatement approaches. The other program is aimed at in-flight determination of pilot-aircraft system performance as well as pilot describing function and remnant information.

V/STOL AIRCRAFT CONTROL/DISPLAY CONCEPT FOR

MAXIMUM OPERATIONAL EFFECTIVENESS
Kenneth W. McElreuth, James A. Klein (Collins Radio Co.), and
Ralph C. Thomas (Colline Radio Co.) /n AGARD Advan. in Control Systems May 1974 8 p refs (For availability see N74-31429 21-02)

Vertical/Short Takeoff and Landing (V/STOL) aircraft and their unique missions define four requirements for a practical and sultable IFR control/display system: (1) maximum flight profile flexibility. (2) flight control precision, (3) low pilot workload and (4) simplicity at low cost. A system concept which has made significant progress in meeting these requirements is described. The system concept is that of retaining the human pilot as an active control element, augmented by an integrated system of displays, steering computation, and automatic control elements. The task allocation between the pilot and the automatic portion of the system optimizes the pilot's flexibility and control effectiveness in the control tasks for which he is most suited complemented by the precision and reduction in workload afforded by automatic control techniques. The approach taken in the development of the system was to first define the mission tasks to be performed and the system constraints. Analysis and pilot-in-the-loop simulation determined the most effective control scheme and the optimum human-automatic interface. Flight testing then validated the system concepts in hardware form aboard a CH-3E helicopter test bed.

ment, Boscombe Down (England)
COMPARISON OF THE SPIN AND LOW INCIDENCE
AUTOROTATION OF THE JAQUAR STRIKE AIRCRAFT
R. J. Blamey /// AGARD Stall/Spin Probl. of Mil. Aircraft Jun. 1976 10 p. refs (For availability see N76-29245 20-08)

From the extensive flight trials on Jeguar high incidence and spin behavior, a number of interesting results emerged. Compared is the classical high incidence spin mode with a rather less common low incidence autorotation which appeared during Jacquar avaigation trials

N76-29249 British Airgraft Corp., Preston (England) A COMPARISON OF MODEL AND FULL SCALE SPINNING CHARACTERISTICS ON THE LIGHTNING

B R A Burns // AGARD Stall/Spin Probl. of Mil Aircraft Jun 1976 12 p (For availability see N76-29245 20-08)

Lightning spinning history is reviewed and a comparison is made of the characteristics as shown by vertical wind tunnel, helicopter drop model and full scale flight trials. The comparison is made in terms of both qualitative interpretation of the spin and recovery behavior and measured data. It is shown that the three types of tests exhibited good qualitative agreement in all important respects. Only a limited quantitative comparison is possible because of limitations of the measured data and differences between the test techniques. The test results are related to service experience and some observations are made about the interpretation of spinning test results and the need for simplicity in pilot's operating notes.

N76-29250 Northrop Corp., Hawthorne, Calif. DESIGN TECHNOLOGY FOR DEPARTURE RESISTANCE OF FIGHTER AIRCRAFT Aircraft Div.

A fittrigg, Jr., J. S. Ackerman, and A. M. Skow. //n AGARD Stall/ Spin Probl. of Mil. Aircraft. Jun. 1978. 13 p. refs. (For availability see N78-29245 20-08)

Methods are presented for predicting departure characteristics of aircraft during the design stages prior to model or flight tests. The significance of longitudinal pitching moment characteristics with respect to sideslip is discussed and correlated with flight test data. The use of departure parameters is discussed and examples are presented which show good correlation with flight test results. A computer graphics display of the aircraft driven by actual flight test data his proven to be extremely helpful in visualizing complex motions of an aircraft. In particular this technique shows great promise in alding both pilots and engineers in describing disorienting post stall gyrations that may be encountered during stell/spin flight testing of an aircraft. N76-29251* National Aeronautics and Space Administration. Langley Research Center, Langley Station, Va. RESULTS OF RECENT NASA STUDIES ON SPIN RESIST-ANCE

Joseph R. Chambers, William P. Gilbert, and Sue B. Grafton. In AGARD. Stall/Spin Probl. of Mil. Aircraft. Jun. 1976. 12 p. refs. (For availability see. N76-29245.20-08)

Some of the factors which contribute to good stall/spin characteristics of a current fighter configuration indicate that the design of airframe components for inherent spin resistance is very configuration dependent and that few generalizations can be made. Secondary design features, such as fuselage forsbody shape, can have significant effects on stability characteristics at high engles of attack. Recent pilloted simulator studies and airplane flight tests have indicated that current automatic control systems can be tailored so as to provide a high degree of spin resistance for some configurations without restrictions to maneuverability. Such systems result in greatly increased pilot confidence and increased tactical effectiveness.

OF WIND TUNNEL TEST RESULTS ON AIRCRAFT SPINS
[APPLICATION DES MESURES DE COEFFICIENTS AERODYNAMIQUES STATIQUES ET DYNAMIQUE A DES
RECOUPEMENTS PAR CALCUL DES VRILLES OBTENUES
EN SOUFFLERIE]

Marc Vanmarisart /n AGARD Stall/Spin Probl. of Mil. Aircraft Jun. 1975 9 p in FRENCH (For availability see N78-29245 20-08)

A conventional light aircraft model with afficient control surfaces and comparatively easy spin characteristics was used to validate the modelling of spin maneuvers by correlating vertical wind tunnel results with static and dynamic aerodynamic coefficients. It was first concluded that these coefficients must be measured while the aircraft is in continuous rotation; these measurements must take into account the efficiency of the control surfaces, which is itself strongly affected by the general flow pattern, and are only applicable to the case of comparatively mild spins in the case of modern military aircraft, however, spins are usually more complex and violent, and measurements of forced oscillations while the model is in continuous rotation should presumably be included.

STALL BEHAVIOR AND SPIN RSTIMATION METHOD BY
USE OF ROTATING BALANCE MEASUREMENTS
Ermanno Sazzocchi In AGARD Stall/Spin Probl. of Mil. Aircraft
Jun. 1976 16 p. For availability see N76-29245 20-08)

Experimental work is reported in the field of wind tunnel investigation of stall behavior, in the evaluation of the characteristics of lateral control devices, in the measurement of the aerodynamic coefficients to determine lateral-directional stability and the analytical study of the spin. This research has required the development of special test equipment, measurement methods and calibration systems. A description and data is given on the test equipment adopted, its use and some of the results obtained.

N76-29254 Ghent Univ (Belgium). STABILITY OF HELICOIDAL MOTIONS AT HIGH INCIDEN-CES

F. C. Haus. In AGARD. Stall/Spin Probl. of Mil. Aircraft. Jun. 1976. 20 p. (For availability see N76-29245. 20-08).

Mathematical solutions are found for three kinds of problems. (1) to compute the equilibrium condition of steady motion, when the aircraft follows a helicoidal descending path around a vertical axis; (2) to establish the linear equations governing perturbations about the steady state, and to determine the characteristic modes of the resulting motion; and (3) to integrate the nonlinear equations of motion and to determine the manner in which an sircraft can reach a steady state motion, or depart from it - (entry into or redovery from a spin). Such mathematical operations provide insight into the mechanics of spiniting motion even though serodynemic coefficients are not known very accurately at the present time.

EFFECTS OF AIRFRAME DESIGN ON SPIN CHARACTERISTICS [EVOLUTION DES CARACTERISTIQUES DE LA
VINILLE EN FONCTION DE L'ARCHITECTURE DES
AVIONS]

Jean Gobeltz In AGARD Stall/Spin Probl. of Mil. Aircraft Jun. 1975 15 p. In FRENCH (For availability see N78:29245 20-08)

The offacts of changes in the airframe geometry during the last few decades on aircraft spin characteristics were reviewed. The type of aircraft considered ranged from low speed, pre-world war it, propeller driven aircraft, through the early jet aircraft with moderate sweepback, to the most recent jet aircraft with pronounced sweepback. The contribution of the various sufframe components such as control surfaces, flaps, airbrakes, fins fusalage, wings, atc. was discussed in addition to other relevant factors such as inertial characteristics, external loads, rockets, etc. Special emphasis was placed on the Mirage 3 and Lightning aircraft.

ASYMMETRIC AERODYNAMIC FORCES ON AIRCRAFT AT HIGH ANGLES OF ATTACK - SOME DESIGN GUIDES

Gary T Chapman, Earl R. Keener, and Gerald N. Malcolm In AGARD Stell/Spin Probl of Mil. Alteraft Jun. 1876 9 p refs (For availability sea N76-29245 20-08)

Aerodynamic side forces on forebodies are considered that are produced by two types of flow: asymmetric vortices on bodies of revolution and nonuniform flow separation on square bodies with rounded corners under spinning conditions. Steady side forces that can be as large as the normal force are produced by asymmetric voitices on pointed forebodies. This side force has a large variation with Reynolds number, decreases rapidly with Mach number, and can be nearly eliminated with small note bluntness or strakes. The angle of attack where the side force first occurs depends primarily on body geometry. The theoretical techniques to predict these side forces are necessarily semiempirical because the basic phenomenon is not well understood. The side forces produced by nonuniform flow separation under spinning conditions depend extensively on spin rate, angle of attack, and Reynolds number. The application of simple crossflow theory to predict this side force is inadequate much below angles of attack of 90 deg.

CBCL 01C

Unique test techniques and facilities are reported which are used to predict the stall/spin characteristics of highly maneuverable military alreaft. Three of the more important test techniques are: (1) flight tests of dynamically scaled models: (2) rotary balance tests; and (3) piloted simulator studies. Recent experience has indicated that the extension of piloted simulation techniques to high engles of attack provides valuable insight as to the spin susceptibility of fighter configurations during representative air combat maneuvers. In addition, use of the technique is an effective method for the development and evaluation of automatic spin prevention concepts.

EFFECTS OF STATIC MOMENTS FROM ROCKETS OR
ASYMMETRIC LOADS ON AIRCRAFT SPINS (ACTION SUR
LA VRILLE, PAR MOMENT STATIQUE, DE FUSEES ET DE
CHARGEMENTS DISSYMETRIQUES)

Jean Gobeltz and Lucien Beaurain In AGARD Stall/Spin Probl. of Mil. Aircraft Jun. 1976 11 p refs in FRENCH (For availability see N76-29245 20-08)

Vertical wind tunnel test results performed on different scale models to investigate alicraft spin maneuvers were discussed. Two areas were considered (1) the use of rockets carried on alicraft, to be fired as an emergency device during spins. The application of this concept has so far been limited to light aircraft, although certain qualitative conclusions may be valid for other types of aircraft, including military aircraft, (2) the influence of asymmetrical loads on spins for aircraft of all types: military, ilight, transport. In the case of military aircraft, geometrical asymmetries were also discussed.

Claudius LaBurthe In AGARD Stall/Spin Probl. of Mil Aircraft

Claudius LaBurthe In AGARD Stall/Spin Probl. of Mil Aircraft Jun. 1976 9p in FRENCH; ENGLISH summary (For availability see N76-29245 20-08)

Relatively few aircraft are lost owing to sinking, stalling or spinning. Among other reasons, this favorable result may be attributed to a particular emphasis put on pilot instruction about aircraft behavior at high angles of attack. But in view of the unfavorable influence of wing loading this situation might deteriorate with new aircraft. Some test results are analyzed as regards the nature of losses of control. The major influence of linetia is thus demonstrated. Limits of credibility for stall warning systems, based upon angle of attack manuscreent, are then deduced.

Charles A. Sewell and Raymond D. Whippler In AGARD. Stall/Spin Probl. of Mil. Aircraft. Jun. 1976. 7 p. refs (For availability see N76-29245-20-08).

The evaluation of various spin prevention design concepts for the F-14 Tomost by analytical, simulational, and experimental methods is described. Preparation of the test vehicle is detailed showing unique emergency systems and qualification testing of these systems. Operational aspects of the flight test program including the problem devising a system flexible enough to permit in-flight optimization of design parameters is treated. The gradual shift in emphasis from spin prevention, which was accomplished with relative case, to departure amelioration for enhanced air combat effectiveness is documented. An overview of the final ARI with associated subsystems is given.

N76-29265 General Dynamics/Fort Worth, Tex YF-16 HIGH ANGLE OF ATTACK TEST EXPERIENCE John P. Lamers In AGARD Stell/Spin Probl. of Mil. Aircraft Jun. 1976 14 p. (For availability see N75-29245 20-08)

The objective of high angle of attack flight tests was to clear the aircraft for the air combat maneuvering test phase. This was to be accomplished by validation of predicted aerodynamid date, and a comprehensive evaluation of handling qualities and flight control system performance during aggressive simulated tactical maneuvering. The program also included a realistic evaluation of the effectiveness of special automatic control system features designed to enhance high angle of attack maneuverability. handling qualities, and departure resistance. Of particular interest were the effects of the active control system (command and stability augmentation) and relaxed static stability concepts upon stall/spin characteristics and recovery capability. Engine operating characteristics at high angle of attack, high angle of sideslip, low airspeed conditions were also of interest. Results show excellent high angle of attack flight characteristics, good correlation with NASA spirr model results, and normal flight control system operation over the range of conditions tested.

AFFECTS OF FLOW TURBULENCE AND NOISE AND AFFODYNAMIC PHENOMENA AND WINDTUNNEL RESULTS

R. Michal In AGARD Large Windtunnels: Required Characteristics and the Performance of Various Types of Transonic Facility Jun. 1974 27 p refs in ENGLISH and FRENCH (For availability see N74-31733 21-11)

An account is given of the influence of stream turbulence and noise on transition in laminar boundary layers and on the development of boundary layers that are already turbulent. This is followed by a discussion of the effects of turbulence and noise on wind tunnel measurements of overall force and moment coefficients and on phenomena associated notably with interactions between shockwaves and boundary layers. These considerations are vital to the extrapolation of wind tunnel results to full-scale conditions and to the specification of Reynolds number and flow quality requirements for future aerodynamic testing facilities

WINDTUNNELS: SOME GENERAL PRINCIPLES
P. G. Pugh In AGARD Large Windtunnels: Required
Characteristics and the Performance of Various Types of Transonic Facility Jun. 1974 22 p. refs (For evailability see N74-31733

The general principles governing the design of a high-Reynolds-number transonic wind tunnel are examined. After a brief review of the essential design aims, the choice of size and operating pressure is discussed. With a rationale for these parameters established, means of schieving them are considered: in particular, the relative merits of various types of drive system

N74-31739 Avions Marcel Dessault-Breguet Aviation, Saint-Cloud (France).

ADDENDUM TO A SURVEY OF CORRECTING WALL CONSTRAINTS IN TRANSONIC WINDTUNNELS

J. C. Vayssaire /// AGARD Large Windtunnels: Required Characteristics and the Performance of Various Types of Transonic Facility Jun. 1974 21 p refs (For availability see N74-31733 21 11)

Methods for correcting wall constraints in transonic wind tunnels are discussed. Using linearized compressible flow theory. the influence of wingspan upon lift interference factors is examined. The streamline curvature correction is also considered, together with the influence of the position of the pressure detum in relation to that of the model. The characteristics of porous walls are considered with the proposal that a porous wall may be calibrated by comparing a test result with theoretical grid results computed for several values of porosity parameter in the boundary

N74-31740 Royal Aircraft Establishment, Farnborough (England). SOME OBSERVATIONS ON OPTIONS FOR A LARGE TRANSONIC WINDTUNNEL

P. G. Pugh and D. Kuechemann In AGARD Large Windtuhnels: Required Characteristics and the Performance of Various Types of Transonic Facility Jun. 1974 6 p refs (For availability see N74-31733 21-11)

The design parameters for transonic wind tunnel development are discussed. The two types of specifications which influence the design parameters are defined. Specific considerations concern: (1) provision for exceptional tests, (2) the quality of the flow, and (3) heat transfer from the wind tunnel model. The effects of flow instability in the wind tunnel are analyzed.

N74-31741 Von Kermen Inst. for Fluid Dynamics, Rhode-Saint-Genese (Belgium)

REVIEW OF SOME PROBLEMS REPATED TO THE DESIGN AND OPERATION OF LOW SPEED WINDTUNNELS FOR V/STOL TESTING, ADDENDUM

M. Carbonaro In AGARD Large Windtunnels: Required Characteristics and the Performance of Verious Types of Transonic Facility Jun. 1974 3 p refs (For availability see N74-31733

(AGARD-R-601)

A method of calculating wall interference in transonic wind tunnels by using a vortex lattice to simulate the wind tunnel walls is discussed. The method includes the effects of wake curvature and wake displacement due to the wind tunnel walls The flow distortions produced by a wind tunnel model are examined with respect to the minimum test speed and the maximum model-to-tunnel dimension ratio. Additional test procedures involving ventilated walls, simulated ground effect, and flow disturbances in the tunnel circuit are briefly noted.

THE NEED FOR A LARGE TRANSONIC WINDTUNNEL IN EUROPE. SECOND REPORT OF THE LANGE WINDTUN-NELS WORKING GROUP

Aug. 1974 46 p refs (AGARD-AR-70) Avail: NTIS HC \$5.50

The Second Report of the Large Windtunnels Working Group of the AGARD Fluid Dynamics Panel is presented. The group confined its further considerations to the need for and definitions of a large transonic windtunnel in Europe. The angineering studies on the proposed four options for the tunnel drive system are reviewed; engineering of all four appears to be feasible but at higher dost than anticipated. The Group still cannot recommend a preferred option technical grounds, but recommends that following further work a selection should be made before the end of 1975. The program of further work necessary to provide the information needed for selection of a preferred option is defined, together with recommendations on how it should be shared between National Programs and on Indepedent Technical Project Group, with coordination as required by the MiniLaWs Group of the Fluid Dynamics Panel It is concluded that the reasons given on the need for a large European transonic windtunnel still apply, and no change is required in the standard specification of the windtunnel

AT THE DESIGN AND OPERATION OF LARGE WIND TUNNELS

Sep. 1975 130 p refs (AGARD-AR-83) Avail: NTIS HC \$8.00

Work completed previously describing projected areas considered to be relevant to the design and operation of large wind tunnels was reviewed in the light of progress made. Comments and recommendations are made. In each one of the four fields of work selected, two conveners, one from each side of the Atlantic, brought together the foremost workers in that field to discuss what needs to be done, how the work should proceed, and how it could be shared. Altogether 132 research workers from nine countries participated and made valuable contributions. Topics of Importance, including some which require particular attention, were also identified and divided into three categories: problems for which sufficient effort is currently being devoted, problems not currently attracting enough attention but where some activities are expected soon, and problems where positive action is necessary.

RADAR DETECTION AND TRACKING IN GROUND

H. D. Mitchell, M. R. Paglee, G. M. Sparks, and G. H. Stevens In AGARD. Range Instrumentation, Weapons Systems Testing and Related Techniques Feb. 1976. 20 p. refs. (For availability sin: N76-23283, 14-09).

The results are presented of a developmental progrem designed to provide automatic detection, acquestion, and tracking of high speed artillery projectiles with an existing C-band precision institution and acquisition of projectiles with a clutter-to-signal ratio of 30 db. In less than one second after firing, projectiles with a clutter-to-signal ratio of 30 db. In less than one second after firing, projectiles when to be tracked through the entire trajectory to near impact. The detection process utilized a recursive digital clutter rejection filter and an EFT processor. Tracking was accomplished using multiple pole fine-line filters in conjunction with clutter guard gates and automatic PRF switching. Preliminary test results inflicate detection and tracking of 18 of the 20 projectiles fired in the test.

THE STRADA LANDING TRAJECTOGRAPHY SYSTEM (LE SYSTEME DE TRAJECTOGRAPHIE D'ATTERRISSAGE STRADA)

Christian Giffard and Jean Pierre Marvillet In AGARD Range Instrumentation, Weapons Systems Testing and Related Techniques Feb. 1976—12 p refs in FRENCH (For availability see N76-23283-14-09)

The STHADA system was developed to accurately reconstruct and display, in near-real time, the trajectories of aircraft during approach and lending and thereby allow the development and curtification of automatic landing systems. The system utilizes modern electron optics techniques in conjunction with a real-time computer integrated with an observation system, it is based on the LIDAR laser radar system providing the aphenical coordinates from a passive optical reflector, which is the only special-purpose hardware that must be installed on the avoidft. The required performance specifications, a general description of the STRADA system a dutailed study of its various components, the data reduction techniques, and the role assigned to the computer are described Resolution of the safety problems associated with the laser system and atmospheric signal propagation was explained, as well as information on projected applications. menning, and cost optimization. THE HITVAL PROGRAM INSTRUMENTATION

Robert L Change In AGARD Range Instrumentation, Weapons Systems Testing and Related Techniques Feb. 1976 8 p (For availability see N76-23283 14-09)

The HITVAL Program, a joint U. S. Army and Air Force test sponsored by the Director of Defense Research and Engineering (DDR&E), was conducted to determine the probability of hit by antiaccraft gun systems firing at fixed-and rotary wing alteralt. The HITVAL test was one element of a larger program to volidate and improve mathematical aircraft attrition models. The HITVAL Program tosted five gun systems and produced a large and comprehensive amprical data base from over two thousand gun aircraft engagements. These data also have possible application to problems of tactics, gun system and arew performance, and training. Instrumentation and techniques developed for the HITVAL Program contributed significantly to the state of-the-art in the measurement of gun performance parameters and represent edvances in resolution, accuracies, and data handling for these and other generic systems and for Author Author test programs.

Robert A. Kilgore, Jerry B. Adcock, and Edward J. Ray /n AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 19 p. refs (For availability see N78-25213 18-09) (L-10032) CSCL 14B

Based on theoretical studies and experience with a low speed cryogenic tunnel and with the transonic cryogenic tunnel, the cryogenic wind tunnel concept has been shown to offer many advantages with respect to the atteinment of full scale Reynolds number at reasonable levels of dynamic pressure in a ground based facility. The unique modes of operation available in a pressurized cryogenic tunnel make possible for the first time the separation of Mach number, Reynolds number, and sercelastic effects.

N76-25215 Royal Alteraft Establishment, Bedford (England). THE ECT DRIVE SYSTEM: A DEMONSTRATION OF ITS PRACTICABILITY AND UTILITY

P. G. Pugh, W. A. Beckett, and T. G. Gell. In AGARD. Wind Tunnel Design and Tasting Tech. Mar. 1976. 15 p. refs (For availability see: N76-28213, 16-09).

A description is given of the construction and operation of a small. ECT driven, transonic wind-tunnel. The dynamics of each essential feature of the ECT drive are considered in turn. The flow generated by an ECT drive is shown to be of very high quality. Further, via a discussion of some typical serodynamic tests that have been performed in the tunnel, it is shown that such a high flow quality is not merely a desideratum. Rather, it is an absolute necessity if many important classes of tests are ever to be successfully conducted in large wind tunnels with short running times.

THE LUDWIEG TUBE: A PROPOSAL FOR A HIGH REYNOLDS NUMBER TRANSONIC WIND TUNNEL

H. Ludwieg, H. Grauer-Carstensen, and W. Lorenz-Mayer In AGARO Wind tunnel Design and Testing Tech. Mar. 1975 11 p. refs (For availability see N78-25213 16-09)

After a brief review of the historical development of the Large European High Reynolds Number Tunnel (LEHRT) and Itä specifications the advantages and flexibility of a Ludwieg tube drive system are outlined. Special emphasis is given to the development of the boundary layer in the charge tube and its influence on the flow quality in the test section. The theoretical predictions of boundary layer growth are confirmed by experimental results. An improved prediction method for the turbulence in

09 RESEARCH AND SUPPORT FACILITIES (AIR)

the test section is given. Means to affect the turbulence in order to meet the LEHRT requirements are outlined. After a short review of the development of cost estimates some options are discusted which promise significant reduction in construction costs without impairing performance. These solutions are the application of prestressed concrete for large parts of the construction, lowering the stagnation temperature by an amount of approximately 50 C, and operation at cryogenic temperatures.

INDUCTION WIND TUNNEL PERFORMANCE: TEST SECTION FLOW QUALITY AND NOISE MEASUREMENTS J. Rom, J. Braits, and A. Seginer In AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 8 p. refs (For availability see N76-28213 16-09)

Flow quality measurements obtained in the 80cm x 80cm IDT are presented and discussed with particular emphasis on the noise and pressure fluctuations. Measurements of the flow uniformity in the test section, over the Mach number range of 0.4 to 1.15 obtained by the operation of a circumferential injector. are presented. Extension of the Mach number range to low aupaisonic Mach numbers is discussed. Measurements of turbulence by a hot wire system are presented showing that the turbulence level is between 0.5 to 10. The high turbulence level at the nozzle walls decays to a reasonable level at a distance of less than 5cm from the walls. Noise measurements were performed using microphones installed in various positions in the test section, injector exit and first diffuser. Model vibrations ware measured by high speed photography. The vibrations are found to depend on the natural frequency of the model sting balance system. When this frequency is in the vicinity of 20 to 30Hz, resonance vibrations are excited by the injector pressure fluctuations that are concentrated in this low frequency range. The overall flow steadiness is demonstrated by results of buffet onset measurements on a model of a delta wing simplane which correlated well with the flight test results

NOISE AND FLOW MANAGEMENT IN BLOWDOWN WIND
TUNNELS

Edward L Whitfield In AGARD Wind Tunnel Design and Testing Tech, Mar. 1976 7 p. refs (For availability see N76-25213

A 4-foot blowdown wind tunnel was designed to specifications oriented almost exclusively toward supersonic operation, with the result that flow quality at subsonic and transonic speeds was unduly compromised. Several recent tunnel modifications, designed to correct this deficiency, have resulted in a reduction of the test section pressure unsteadiness such that the present level compares favorably with that found in closed circuit, continuous wind tunnels. Experimental efforts with a 1/12-scale model tunnel, used for the purpose of establishing suitable modifications, are recounted. Model and full scale tun-il data indicate that a significant reduction in throttle valve induced noise levels can be obtained by breaking up the valve discharge flow into a large number of small jets. This approach yields low turbulence flow even with a pressure ratio across the valve as large as 30:1.

LOW SPEED TUNNELS WITH TANDEM TEST SECTIONS:
A CONTRIBUTION TO SOME DESIGN PROBLEMS

Bernd Eweld In AGARD Wind Tunnel Design and Testing Tach Mar 1976 14 p refs (For availability see N76-25213 16-09)

The building expenses of a low speed wind tunnel are a function of test section size and maximum speed. During the design of the tunnel a combination of both must be chosen which gives the best cost effectiveness for the proposed use of the tunnel. The main disadvantage of the tandem test section layout is its great overall length. Minimum required length of undisturbed test section flow field was derived from various test requirements and model scale considerations. Modern numerical flow held calculation methods were used to find out the test section flow field distortion induced by the main nezzle and the intermediate nozzla between the test sections. Optimum nozzle designs for uniform exit velocity induce considerable flow field distortions upstream into the settling chamber respectively into the large test section in the case of the intermediate nozzle of a tandem test section layout. This upstream distortion may be compensated to some extent by a slight expansion at the rear end of the first test section. Calculated results for this compensation are given. Another contribution to minimum overall length may be found in the design of the settling chamber. A novel design of cooled honeycomb gives the required cooling performance in combination with low drag and good flow quality. In combination with this study a wide variety of wind tunnel cooling schemos was investigated in detail; results and criteria for the final selection of the cooling system are included.

N76-25221 National Aerospace Lab., Amsterdam (Netherlands), DESIGN AND CALIBRATION OF THE 1/10TH SCALE MODEL OF THE NLR LOW SPEED WIND TUNNEL LST 8X6

J. C. A. VanDitshuizen //n AGARD Wind Tunnel Design and Testing Tech Mar 1976 14 p refs (For availability see N76-25213 16-09)

A model was built at scale 1:10 of the LST 8x6 wind tunnel to investigate the aerodynamic design features and provide additional information concerning unconventional items such as a throttle for augmentation of the circuit loss factor and a system for intermittent ventilation. The design philosophy is outlined, followed by a survey of the results of the calibration. Where possible theoretical predictions and experimentally obtained data have been compared. The results indicate that the requirements which are set for the full scale tunnel will be met.

N76-25222 Dornter-Werke G.m.b.H., Friedrichshafen (West Germany). HIGH-PERFORMANCE COMPACT WIND TUNNEL DE-BION

Ernstfried Thiel In AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 6 p (For availability see N76-26213 16-09)

Optimum conception and geometry of a large low speed wind tunnel, which will be equipped with two test sections of different size in order to enlarge the operational spectrum, is discussed. For a conventional wind tunnel type with a closed circuit two possibilities lend themselves to the test section arrangement, the tendem configuration or a system of exchangeable test sections. An optimum solution with regard to construction volume, economic utilization of the installed power, and good flow quality led to the idea of the multitube multifan compact wind tunnel, a configuration in which each of the two different test section areas is linked with a corresponding number of diffuser tubes, each of which end after the first two corners in a separate fan with an adjacent diffuser.

N76-25223* National Aeronautics and Space Administration Amas Research Center, Molfett Field, Calif THE RATIONALE AND DESIGN FEATURES FOR THE 40 BY 80/80 BY 120 FOOT WIND TUNNEL

K. W Mort, M W Kelly, and D H Hickey In AGARD Wind Tunnel Design and Testing Tech Mar 1976 5 p refs (For availability see N76-25213 16-09)

A substantial increase in the test capability of full scale wind tunnels is considered in order to determine the most cost effective means for providing this desired increase in test capability a series of design studies were conducted of various new facilities as well as of major modifications to the existing 40- by 80 foot wind tunnel. The most effective trade between test capability and facility cost was provided by repowering the existing 40- by 80 foot wind tunnel to increase the maximum speed from 200 knots to 300 knots and by the addition of a new 80- by 120-foot test section having a 110 knot maximum speed. The

design of the facility is described with special emphasis on the unique features, such as the drive system which absorbs nearly four times the power without an increase in noise, and the large flow diversion devices required to interface the two test sections to a single drive.

EXPERIMENTS WITH A SELF-CORRECTING WIND TUN-

R. J. Videl, J. C. Erickson, Jr., and P. A. Catlin. In: AGARD Wind Tunnel Design and Testing Tech. Mair. 1976. 13 p. refs. Sponsored in part by NASA and the AF (For availability see N76-25213 16-09).

(Contract N00014-72-C-0102)

The feasibility of controlling the flow actively through the walls of a transonic, porous wall wind tunnel in order to minimize wall interference effects on a test model is demonstrated. The method is based upon measuring the components of the disturbance velocity at discrete points along an in aginary surface in the flow field within the tunnel. A mathematical formulation of the flow field exterior to the surface including the boundary condition for unconfined flow, i.e., that all disturbance vanish at infinite, is used to determine if these measured velocity components are consistent with that boundary condition. If they are not, the theory provides a better approximation to the velocity component for unconfined flow, and the flow through the tunnel walls is readjusted iteratively until the measured quantities are consistent with unconfined flow. A buef review of theoretical methods is followed by a description of the Calspan self correcting wind tunnel design and operation, calibration with and without active wall control. Typical results obtained by approximating a conventional porpus wall wind tunnel for an 0012 airfol show that active wall control largely reproduces the correct shock wave position, eliminates wall interference of lift and drag, and reduces the interference effects on pitching moment to 10%.

ADAPTIVE WALL TRANSONIC WIND TUNNELS

Jean-Pierre Chevallier In AGARD Wind Tunnel Design and Testing Tech. Mar 1976 8 p. refs. in FRENCH, ENGLISH summary (For availability see N76-25213 16-09)

To remedy the difficulties at application of wall correction effects in high transonic flow with nonlinear phenomena, a new concept has been proposed. It consists in an active control of the perturbation component normal to the wall, based on the iterative calculation of the virtual flow in an unlimited domain outside the tunnel section. The paper deals with the principle and the application means of the new testing process, preliminary study of a pilot facility, the first results obtained in two dimensional flow, and the conclusions concerning the development of this process.

A LOW SPEED SELF STREAMLINING WIND TUNNEL

M. J. Goodyer. In AGARD. Wind Tunnel Design and Testing Tech. Mar 1976. 'p refs. Sponsored by NASA (For availability see N76-25213.1...19).

A two dimensional test section in a low speed wind tunnel is producing flow conditions free from wall interference. The test section has flexible top and bottom walls, and rigid sidewalls from which the models are mounted spanning the tunnet. All walls are unperforated, and the firstble walls are positioned by screw jacks. To eliminate wall interference, the wind tunnel itself supplies the information required in this streamlining process. when no with the model present. Measurements taken at the flexible walls are used by the tunnel computer to check wall contours. When the static pressure distribution in the test section along a contoured flexible wall matches that computed for an imaginary flow field passing over the outside of the same contour, the wall is a streamline in an infinite flow field and the test section flow is free from wall interference. A series of iterations brings the walls from straight to streamlines. Illustrative serodynamic data is presented, taken on a bluff body and a lifting wing

N76-26227 National Aerospace Lab., Amsterdam (Netherlands) THE EFFECT OF FINITE TEST SECTION LENGTH ON WALL INTERFERENCE IN 2-D VENTILATED WIND TUNNELS

J W Sleeff and W. J. Piers In AGARD Wind Tunnel Design and Testing Tech Mar. 1976 11 p refs (For availability see N76-25213 16 09)

The effect of the ventilated wells on the flow in the wind tunnel is usually described by a so called homogeneous boundary condition. In the classical approach a linear hip cities used which is further based on the assumption that the ventilated wells are of infinite length. The classical theory has been extended to include a modification, which makes it possible to take into account the limite length of the test section, inclusion of higher order effects leading to a consistent second order theory. The results indicate that the length to height ratio of the test section is an important parameter in ventilated wall interference, model position and plenum pressure can be used to minimize wall interference effects.

INFLUENCE FUNCTION METHOD IN WIND TUNNEL WALL INTERFERENCE PROBLEMS

M. Mokry In AGARD Wind Tunnel Design and Testing Tech Mar. 1976 10 p. refs (For availability see N76 25213 16-09)

A new general method is described for computation of wind tunnel wall interference effects in subsonic linearized flows. The influence function, introduced as a fundamental solution satisfying the prescribed wind tunnel boundary conditions, plays the central role in the present analysis. The method is applied to subsonic flow past an airfoil between perforated walls, and compared with measurements from the 15 in. x 60 in test section of a 5 ft blowdown wind tunnel. Further examples concern a multi-component airfoil, finite cascades of blades, and the vortex sheet rollup behind a wing in a wind tunnel.

WALL CORRECTIONS FOR TRANSONIC THREE-DIMENSIONAL FLOW IN VENTILATED WIND TUNNELS Xavier Vaucheret and Jean-Charles Vayssaire (Avions Marcel Dessault) In AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 18 p. refs. In FRENCH, ENGLISH summary (For availability see N76-25213 16-09)

After a brief explanation of the necessity for well corrections, two methods for calculating correction factors are then considered, the analytical method and the vortex lattice method. The expected accuracy and some practical examples demonstrate the possibilities of these two methods. The methods for defining wind tunnel ventilated walls are analyzed. The detailed method for obtaining the law to define aerodynamic permeability as a function of Mach number is thoroughly explained. Examples applied to industrial tests demonstrate the methods used. Criteria based on the confidence level which can be grated to correction permit graphs to be plotted for defining the size of wind tunnel models.

N73-25230 Aeronautical Research Inst. of Sweden, Bromma. FLOW PROPERTIES OF SLOTTED WALLS FOR TRANSONIC TEST SECTIONS

Sune B Bendt and Hans Soeronsen In AGARD Wind Tunnel Design and Testing Fech Mar 1976 11 p refs (For availability see N76-25213 16 09)

(Grant AF-AFOSR-2184-72)

A theoretical and experimental study is reported on flow through slotted walls under a variety of conditions. The ultimate objective is to make possible accurate numerical computation of transonic flows around models in slotted test sections. Considered is slot flow configuration typical of two dimensional, low lift tests at high aubsonic free stream Mach numbers. With the test section empty the slot flow is outwards, into the plenum chamber, and this remains true over a large part of the test section when the model is introduced. From oil flow plotures and pressure measurements in and around the slots it is concluded: that the slot flow is slightly influenced by the presence of the wall boundary layer, that the flow within the slot is attached and approximately inviscid although influenced by boundary layer formation, that the flow enters the plenum chamber as a thin free jet, and that the transverse velocity in the jet and slot is too large for a linear pressure drop equation to be sufficiently accurate. When the slot flow turns back over the rear and of the model it may admit stagnant air from the plenum chamber into the test section; the ability of the slot to maintain a pressure difference across the wall is then necessarily reduced. Based on these observations a tentative flow model is proposed, yielding a relationship between

EXPERIMENTS TO ASSESS THE INFLUENCE OF CHANGES IN THE TUNNEL WALL BOUNDARY LAYER ON TRANSONIC WALL CROSSFLOW CHARACTERISTICS

R. F. Starr In AGARD Wind Tunnel Design and Testing Tech.
Mar. 1976 11 p refs Sponsored by the AF (For sveilability see N76-25213 16-09)

The equivalent porosity of the test section wall in a transonic wind tunnel with a fixed geometric porosity and verying wall boundary layer displacement thickness, has been investigated. Previous experiments have demonstrated that the boundary layer displacement thickness on the wall influences the wall crossflow characteristic Experimental data from a Ludwieg tube type of transonic tunnel are compared to data from conventional transonic tunnels in the Mach number range from 0.95 to 1,15. The displacement thickness studied is comparatively thin and represents typical values which will be encountered in future high Reynolds number transonic tunnels. Based on the change in static pressure measured on a cone cylinder model, it is shown that a factor of two variation in the tunnel wall displacement thickness results in an equivalent wall porosity change of less than one percent in the range 0.13 less than or equal to displacement thickness/d less than or equal to 0.28, where d is the wall hole diameter.

THE COMPUTATION OF TRANSONIC FLOWS PAST AEROFOILS IN SOLID, POROUS OR SLOTTED WIND TUNNELS

D. Catherall In AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 10 p. refs (For availability see N76-25213 16-09)

A method is described for computing two dimensional inviscid flows at transonic speeds in wind tunnels in which the transonic small perturbation equation is solved. Because of the use of coordinate transformations, which transform the infinite physical plane into a finite computing one, far field boundary conditions are relatively easy to obtain and apply. The effect of tunnel walls on the flow has been modelled by using the usual homogeneous wall boundary condition. Comparisons are made with some experimental results and the free air and tunnel versions are used to assess the sbillity of linear subsonic theory to predict tunnel interference corrections when the flow is transonic.

O. DeVnes and G. J. L. Schipholt *In* AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 7 p. refs (For availability see N76-2/:213 16-09)

A singularity method has been applied to calculate two dimensional tunnel wall corrections for multi-element serofolis. The calculations show, that the well known corrections due to Glauert can be applied for a single serofoli, except the pitching moment correction above 15 deg angle of attack, but that the Glauert approach fails in the case of trailing edge flap deflections. The results of the calculations agree with the strong non linear results found by De Jager and Van de Vooren for a hinge. Author

A LOW-CORRECTION WALL CONFIGURATION FOR AIRFOIL TESTING

C. D. Williams and G. V. Parkinson. In AGARD. Wind Tunnel Design and Testing Tech. Mar. 1976. 7 p. refs (For availability see N76-25213 16-09)

The reduction of wind tunnel wall corrections in airfoil testing by a transversely slotted wall opposite the suntion side of the test airfoil, and by a solid wall opposite the pressure side, is considered. The solid elements of the slotted wall are symmetrical airfoils at zero incidence. This geometry permits the flow to assume closely the streamfline pattern for unconfined flow, without degrading the flow quality through shear layer mixing near the test airfoil. The theory uses the potential flow surface source/element method, with Kutta conditions satisfied on the test airfoil and the wall slats. In experiments using a range of sizes of airfoils of three different profiles, good agreement with the predictions of the theory has been obtained. It appears that

the pressure difference across the wall and the transverse velocity through the slots

DETERMINATION OF LOW SPEED WAKE BLOCK AGE CORRECTIONS VIA TUNNEL WALL STATIC PRESSURE MEASUREMENTS

E. Hankett and D. J. Wilsden. In AGARD. Wind Tunnel Design and Testing Tech. Mar 1976 9 p. refs (For availability see N76-25213 18-09)

A theoretical method has been defined for determining wind tunnel solid/bubble and viscous blockage from wind tunnel wall and roof pressure measurements involving lifting or non-lifting. powered or unpowered models. Three finite span line sources are used which are defined by five geometric and two flow parameters. Matching these parameters to the measured interim by an engineering solution is suggested. The method has been applied successfully to blockage calculations for a series of normal flat plates. Other experimental results, involving more typical wind tunnel models are also discussed.

N76-25236 Deutsche Forschungs- und Versuchsanstalt füer Luft- und Raumfahrt, Cologne (West Germany) IMPROVED DISPLACEMENT CORRECTIONS FOR BULKY MODELS AND WITH GROUND SIMULATION IN SUBSCINIC WIND TUNNELS

Gerhard Schulz In AGARD Wind Tunnel Design and Testing Tech Mar. 1976 7 p. refs (For availability see N76-25213 16-091

Wind tunnel measurements have to be corrected owing to the finite dimensions of the test section. There are several kinds of corrections, namely displacement or dynamic pressure corrections, downwash or direction corrections, and pressure gradient corrections. The numerous publications known on this subject do not state anything about the tolerable displacement up to which the corrections are still reasonable. This work presents quantitative and physically founded statements about this point. The decisive cognition is that, in the case of too large a blocking, the corrections take markedly different values for different parts of the model surface (inhomogeneity of dynamic pressure). The results may be summarized as follows. (1) big displacement has to be avoided, (2) bulky models produce in general considerably larger corrections than bodies of revolution of equal displacement, unless special cases are considered, (3) eccentric position of the model increases the corrections and the inhomogeneity, and (4) inhomogeneity cannot be corrected

TED WALLS OF A TRANSONIC WIND TUNNEL

Xavier Vaucheret In AGARD Wind Tunnel Design and Testing Tech. Mar. 1978 10 p. refs. In FRENCH: ENGLISH summary (For availability see N76-25213 16-09)

In order to reduce the noise level due to the acoustic perturbations generated by the wall perforations in the transonic test section, a classification of the noises emitted by several ventilated panels inserted in the test section was established. For this experimentation, the horizontal perforated walls are closed with adhesive tapes covering the holes. A solution consists of glying, inside the test section a plastic gauze with small mesh on the original walls. The advantage of this solution is the conservation of the original walls. It allows reducing the noise to a level similar to that measured for solid, i.e. closed, wall.

N76-25238 Bosing Commercial Airplane Co. Seattle, Wash NACELLE-AIRFRAME INTEGRATION MODEL TESTING FOR SIMULATION AND MEASUREMENT

R Decher, W B Gillette, and D C Tageler In AGARD Wind Tunnel Design and Testing Tech Mar 1976 14 p refs (For availability see N76-25213 16-09)

Techniques necessary to achieve high accuracy in simulation and in force data for better subsonic airplane nacelle airframe integration are discussed. The selection of the appropriate nacelle simulation is covered together with experimental data obtained with flow, blown, and turbopowered nacelle models operated at wind tunnel flow conditions. The thrust calculation and the simulator calibration procedure are described. To guide test instrumentation and test procedures an error analysis is reported which shows that predicted error levels of under 1% of model simplane dreg can be achieved in the wind tunnel. Data from an isolated and an installed tost with flow, blown, and turbopowered simulator models of a high bypass engine nacelle on a four engined subspiric transport are shown to verify the validity of the test procedures.

AIR DRIVEN EJECTOR UNITS FOR ENGINE SIMULATION IN WIND TUNNEL MODELS

R. Whitaker, A. W. Mutthews, P.G. Knott, R. Angel, and D. J. Stewart In AGARD Wind Tunnel Design and Testing Tech Mar 1976 15 p refs (For availability see N76-25213 16-09)

The air driveri ejector as a means of providing engine flow simulation is discussed. The characteristics of the ejector and its ability to simulate a wide range of engine types and flight conditions are outlined. It is shown that one dimensional theory with empirical loss factors now permits accurate performance predictions to be made. Recent experimental work has extended the scope of the empirical knowledge, demonstrated the merits of supersonic primary nozzle ejectors and improved the state of the art of ejector design. In low speed tunnel teating it has been demonstrated that for a high bypass ratio engine simulator good exit velocity profiles can be obtained and the installed performance well predicted under varying external conditions Also, correct exhaust and intake momentum coefficients can be achieved at acceptable tunnel speeds even when using relatively low drive pressures

MEASUREMENT TECHNIQUES FOR JET INTERFERENCE EFFECTS

Jan VonDerDecken and Roland Jous In AGARD Wind Tunnel Design and Testing Tech. Mar 1976 6 p (For availability see N76-25213 18-09)

Three methods are discussed: (1) the sum of jet thrust and aerodynamic forces including jet interference is measured, (2) the jet thrust itself is not weighed, only the aerodynamic forces working on the model including jet interference are measured, and (3) the thrust vector and the aerodynamic forces are weighed separately by two balances. For all three methods an example is presented. A special problem is the correct calibration of the different jet simulation systems under as realistic conditions as possible including the effects of onset flow. For the mentioned three cases, the calibration method is discussed.

INVESTIGATIONS ON A PLATE WITH UNIFORM BOUNDARY LAYER SUCTION FOR GROUND EFFECTS IN THE 3 m X 3 m LOW SPEED WIND TUNNEL OF DEVLA-

R. Wulf /// AGARD Wind Tunnel Design and Testing Tech Mar. 1976 7 p. refs (For availability see N76-25213 16-09)

A plate with uniform boundary layer suction for ground effects measurements is reported. For measurements with different model clearances the ground plate can be moved continuously through the test section. The velocity profile at various positions on the clean ground plate was measured with a total head pressure rake for different suction coefficients. A suction coefficient of C sub Q . 0.0055 is adequate to reach uniform flow with a boundary layer less than 10 mm thick. Depending on the suction coefficient, the flow in the vicinity of the plate is deflected towards the plate by an angle of C sub Q in addition ground effect measurements have been performed on a VTOL model with an engine system of two tip turbine driven fans and cascades to deflect the jet by 90 deg. In a position close to the ground there is a remarkable influence of boundary layer suction Hysteresis effects are reduced by boundary layer suction. Results from measurements with different bank angles of the ground plate are compared Author

HIGH FREQUENCY GUST TUNNEL

Hermann Viets In AGARD Wind Tunnel Design and Testing Tech Mar 1976 8 p refs (For availability see N76-25213 A mechanism is proposed employing unsteady fluidically controlled flapping jets for application to the production of variable frequency gusts in wind tunnels or in ambient air. The besic mechanism is an unsteady jet based on the simple fluidic element and controlled either by an acoustic feedback line between the control ports or by a pair of rotating valves simply constructed from slotted rods. Some advantages of the proposed system are (1) capable of high frequencies: (2) low torque motors required; (3) capable of producing transverse or streamwise gusts. (4) capable of producing nonsinusoidal wave forms; (5) capable of producing programmed transverse disturbunce; (6) prencibed or random phase relationships among the various nozzles; (7) capable of producing uniform flow across the tunnel span, and (8) rotating valves are self-cooling.

DESIGN AND OPERATION OF A LOW-SPEED GUST TUNNEL

R. A. Sawyer In AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 7 p. refs (For availability sue N76-25213 16-09)

The design of a low speed gust tunnel is described. The tunnel can produce sinusoidal, random or sharp edged vertical gust distributions in a horizontal airstream. The horizontal velocity range is 1.5 ms/1 to 18 ms/1 in an open jet of 0.7 m by 1.0 m cross section, and incidence variations are introduced by a linked array of air-foils across the upstream end of the open jet. The random and sinusoidal frequency range is 0 to 20 cs/1, and sharp edged guets of thickness less than 0.1 m over the first meter of the working section may be produced. Four typical experiments conducted in the gust tunnel are described. These are concerned with unsteady pressure and force measurements, oscillatory vibrations, and response to simulated atmospheric gust spectra in the fields of wings, buildings and structures. The usefulness and limitations of the gust tunnel are essessed.

A LABER-DUAL-FOGUS VELOCIMETER FOR WIND TUNNEL APPLICATIONS

R. School and H. B. Weyer In AGARD Wind Tunnel Design and Teating Tech. Mar. 1976 16 p. refs (For svailability see N76-25213 16-09)

The Laser Dual Focus (L2F) velocimeter measures the velocity of small particles as they are normally contained in every fluid. The basic idea is that two light beams are focused to two very small light spots in the measuring volume. Thus, the available laser power is concentrated to a very high light intensity inside the control volume. The result is that flow velocity measurements can be carried out in back scattering up to high velocities even in the proximity of surfaces normal to the optical axis. In wind tunnel applications the L2F method is well appropriated to measure the velocity field around three dimensional models. Using back scattering allows the complete optical device to be built as one compact unit. By means of the L2F method the mean velocity, the mean flow angle, and the turbulence degree of the velocity components in a plane normal to the beam axis may be determined. The paper describes in detail the optical and electronic arrangements, the test procedure, and some tests in wind tunnels and turbomachines.

APPLICATION OF A LASER-DOPPLER-VELOCIMETER IN A TRANS AND SUPERSONIC BLOW-DOWN WIND TURNEL.

F. Maurer, J. C. Petersen, H. J. Pfeifer (ISL), and J. Haertig (ISL) In AGARD. Wind Tunnel Design and Testing Tech. Mar 1978. 8 p. refs (For availability see N76-25213 16-09)

To examine carefully the potential of a laser Doppler velocimeter for the application in trans- and supersonic blow-down wind tunnels, comparative measurements in turbulent supersonic boundary layers have been performed. Mean velocity profiles as well as turbulence distribution profiles in the wind tunnel boundary layer were measured traversing a crossed beam LDV system from free stream conditions to 0.1 mm distance to the wall. Results were compared to measurements of mean velocity profiles using a combined total pressure and temperature boundary layer probe, from which velocity informations could be derived. The agreement is mostly very good. Nevertheless there are some remaining disorepancies which are discussed. The measurements demonstrate the usefulness of the LDV instrument for transonic and supersonic wind tunnel application, the more so as its potential is still developing.

INTERFEROMETRIC MEASUREMENT OF MODEL DEFORMATION

Ronald A. Belz, Winfried H. Goethert, and Bruce W. Somar In AGARD Wind Tunnel Design and Teating Tech. Mar. 1976 7 p. refs. Sponsored by the AF (For availability see N76-25213 18-09)

Laser interferometry is proposed for measuring model orientation and deformation in a high Reynolds number wind tunnel. A multiple beam optical system and signal processing electronic systems are described which measure relative and absolute model motion (displacement and velocity) normal to the illumination wavefront. The method of determining rotation from the relative linear displacement measurements of two retroreflectors mounted flush with the surface is described and examples of reflector placement for model attitude and deformation are presented. The results of preliminary experiments using a two beam optical system are described to illustrate the measuring capabilities of this electro-optical instrument under isboratory conditions. Finally, errors associated with changes in the sir density from no flow to full flow tunnel conditions and density fluctuations during the test are briefly discussed.

MODEL SYSTEMS AND THEIR IMPLICATIONS IN THE OPERATION OF PRESEURIZED WIND TUNNELS

Stanley A. Griffin In AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 13 p refs (For evailability see N76-25213 18-09)

The fessibility of designing multi-piece flow through models for high Reynolds number transonic wind tunnels is considered Six component, high capacity balances are investigated, and a comparison is made of model aeroelastic characteristics in a pressurized tunnel in reference to the seroelastic nature of the flight vehicle. Methods of matching model/airplane deformation are shown, together with a system for measuring model deformation in a wind tunnel. Selected configurations are reviewed with respect to model loads, distortions, and stress, and a summary of recommended fabrication materials is presented. Cost comparisons are made between models for testing in proposed high Reynolds number transonic wind tunnels and present day transonic wind tunnels. The study concludes that models and strain gaged balances capable of running in these facilities can be designed and fabricated at a reasonable cost with present techniques. The study also indicates that options are available to produce close similarity of the model/airplane wing deformation over a broad range of operating conditions.

DESIGN AND CONSTRUCTION OF THE ALPHA JET FLUTTER MODEL

Peter Esch and Theo Windeck In AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 9 p refs (For availability see N76-25213 16-09)

In order to prove flutter safety for the Alpha jet, a flutter model (scale 1.8) was designed and constructed for experimental

investigations in the transonic wind tunnel. For each component of the aircraft an adequate structural solution had to be found in order to fulfill the correct stiffness distribution. The construction was carried out using advanced techniques, e.g. electron beam welding, chemical milling and bonding. The static vibration tests of the complete model were in good agreement with the corresponding test results of the original aircraft. Ahead of the main tests, preliminary tests with the wing and tell isolated were performed in a blowdown wind tunnel for the tests with the complete model a rigid wire suspension was used. In the course of one year several configurations with and without external stores were investigated. The experimental results agreed reasonably with the theoretical calculations

INTERFERENCE PROBLEMS IN V/STOL TESTING AT LOW SPEEDR

Mario Carbonaro In AGARD Wind Tunnel Design and Testing Tech Mar 1976 21 p refs (For availability see N76 25213 16-091

When testing V/STOL models at low speeds several problems arise, in connection with the sharp downward deflection of the wake originating from the highly loaded lifting systems. It is the purpose of this paper to define the various problems and to summarize and compare the obtained results. First, the inclined wake may impinge on the wind tunnel floor and cause a breakdown in the wind tunnel flow uniformity. The testing limitations associated with the occurrence of such phenomenon are discussed for the different cases of a rotor, a jet flap wing, or a single or multiple lifting jet configuration. Wind tunnel boundary corrections account for the real behavior of the wake and an upper limit of their validity has to be assessed. The various existing theores of wall corrections which take into account the deflection and eventually the curvature of the wake are summarized in the various cases of closed onen or ventilated first sections, and comparisons with existing experimental data are made. The limits proposed in the literature for the validity of wall corrections are discussed

THE REMOVAL OF WIND TUNNEL PANELS TO PREVENT FLOW BREAKDOWN AT LOW SPEEDS

R E Hansford In AGARD Wind Tunnel Design and Testing Tech Mar 1976 8 p. refs (For availability see N76-25213

A model rotor was tested at low speed in a wind tunnel to study the problem of flow breakdown. This condition arises from the wake impingement on tunnel floor and wall panels to induce a recirculatory flow upstream. The phenomenon was first reproduced in the closed tunnel for various disc loadings and limiting operating conditions were established. Panels were then selectively removed and it was subsequently shown that it was possible to obtain a representative tunnel flow free from recirculatory interference, at lower advance ratios compared to closed tunnel operation. By cateful venting of a working section it is concluded that a substantial increase in maximum allowable downwash angle can be obtained

VETOL WIND TUNNEL MODEL TESTING: AN EXPERIMEN-TAL ABSESSMENT OF FLOW BREAKDOWN USING A MULTIPLE FAN MODEL

M. J. Cell. In AGARD. Wind Tunnel Design and Testing Tech. Mar. 1976 8 p. refs (For availability see N76 25213 16 09)

Tests have been made with a multilan VSIOL model in two different sized closed test section wind tinnels to investigate the problem of tunnel flow breakdown. The boundary condition of incipient stagnation where the high energy let exhaust first penetrates the tunnel wall boundary layer has been identified for a range of model conditions. Correlation of results in both tunnels and with other work is good and the technique of establishing a flow breakdown boundary by investigating the behavior of the floor vortex, formed by the interaction of the model jet efflux and the tunnel mainstream flow, has been used successfully for a multifan configuration. In addition model forces and moments are recorded in an attempt to estimate minimum testing conditions and to indicate the magnitude of wall constraint effect. Direct companisons are made of longitudinal forces and moments using results from both wind tunnels and a sample of results are presented

N78-25284 Airgraft Research Association Ltd., Bedford (England) FURTHER EVIDENCE AND THOUGHTS ON SCALE EFFECTS AT HIGH SUBSONIC SPEEDS A. B. Haines In AGARD Wind Tunnel Design and Testing

Tech. Mar. 1976 12 p refs (For availability see N76-25213 16-09)

Recent evidence from tests at high subsonic speeds in existing tunnel facilities are reviewed to illustrate the difficulties in extrapolating the data to full scale. The uncertainties can be considerable even for wings currently being developed; the report stresses that these uncertainties affect not only the flow separation characteristics but also the drag in conditions where the flow is attached. None of the evidence detracts from the arguments which lead to the conclusion that there is a need in Europe for a new large pressurized transonic tunnel; but comments are also made as to whether the new theoretical tools, flight tests, further experimental research in existing facilities and modified experimental techniques could be partly used to offset the lack of such a facility in the next decade Author

FLUID DYNAMIC RESEARCH AT NASA-AMES RESEARCH CENTER RELATED TO TRANSONIC WIND TUNNEL DESIGN AND TESTING TECHNIQUES

Lado Muhistein, Jr and Frank Steinle, Jr In AGARD Wind Tunnel Design and Testing Tech Mar 1976 8 p refs (For availability see N76-25213 16-09) CSCL 20D

Fluid dynamic research with the objective of developing new and improved technology in both test facility concepts and test techniques is being reported. A summary of efforts and results thus far obtained in four areas is presented. The four area are (1) the use of heavy gases to obtain high Reynolds numbers at transonic speeds. (2) high Reynolds number tests of the C-141A wing configuration; (3) performance and flow quality of the pilot injector driven wind tunnel; and (4) integration time required to extract accurate static and dynamic data from tests in transonic wind tunnels. Some of the principal conclusions relative to each of the four areas are: (1) Initial attempts to apply analytical corrections to test results using gases with gamma other than 1.4 to simulate conditions in air show promise but need significant improvement; (2) for the C-141A configuration, no Reynolds number less than the full scale flight value provides an accurate simulation of the full scale flow; (3) high ratios of tunnel mass flow rate to injection mass flow rate and high flow quality can be obtained in an injector driven transonic wind tunnel; and (4) integration times of 0.5 to 1.0 sec may be required for static force and pressure tests, respectively, at some transonic test conditions in order to obtain the required data accuracy. HIGH PITCH RATES FOR USE IN SHORT DURATION WIND TUNNELS

E. Atraphji and J. R. Digney *In* AGARD Wind Tunnel Design and Testing Tech. Mar. 1976 10 p. refs (For availability see N76-28213 16-09)

The demand for high Reynolds numbers is being met at some existing pressurized blowdown wind tunnel facilities at the expense of reduced run time. One possible way of maintaining economical utilization of these short duration tunnels is to program the model for faster pitch rates. The influence of high pitch rates on the mean force, moment and pressure data measured on a typical sting mounted model at subsonic Mach numbers of 0.3 and 0.75 was studied. Results show that there is virtually no affect on these measurements at pitch rates as high as lifteen deg/sec.

SYSTEMATICAL INVESTIGATIONS OF THE INFLUENCE OF WIND TUNNEL TURBULENCE ON THE RESULTS OF MODEL

FORCE-MEASUREMENTS
H. Otto In AGARD Wind Tunnel Design and Testing Tech.
Mar 1976 9 p. refs (For availability see N75-25213 16-09)

The influence of wind tunnel turbulence especially on the maximum lift of aircraft models, has been studied by systematical investigations in five low speed wind tunnels. In each wind tunnel, the free stream turbulence was altered by two different grids which could be fixed at the nozzle exit. The test program included hot wire and sphere measurements to determine the free stream turbulence as well as force measurements on wind body models with different flep deflection angles. The results show that the maximum lift coefficient is not simply a function of the effective Reynolds number but depends also on the scale of the turbulence grid. This correlation is approximated by a simple formula.

The Symposium was organized around three subject areas (1) correlation of basic wind tunnel techniques, (2) flight test

HC \$11.00

techniques for correlation, and (3) wind tunnel/flight correlation. Papers were presented which treated spooific studies designed to compare various two and three dimensional wind tunnel facilities, wind tunnel facilities, designed to provide better Reynolds number matches with full scalo, and techniques used to contain wall effects, measure dynamic characteristics and study noise. The state of the art with regard to parameter identification was summarized and the proceedings of the AGARD Flight Mechanics Panel Specialists' Meeting were reviewed. Also treated were methods of measuring scrodynamic characteristics, in flight, of wings, rotors, and special aircraft configured for the acquisition of data not normally available from flight tests. Correlation experience for a broad spectrum of aircraft types was reported it was suggested that good correlation can be obtained if enough attention is given to ground tests. For individual titles, see N76-25267 through N76-25303.

COMPARATIVE TWO AND THREE DIMENSIONAL TRAN-SONIC TESTING IN VARIOUS TUNNELS

Xavier Vaucheret and Maurice Bazin In AGARD Flight/Ground Testing Fac. Correlation Apr. 1976 14 p refs in FRENCH; ENGLISH summary (For availability see N76-25266 15-09)

Testing conditions at transonic speeds and the validity of the data obtained in various wind tunnels were studied. In two dimensional flow, two models of NACA 0012 and supercritical profiles were tested in ONERA S3 Modens and NAE 15x60 in. tunnels for Reynolds number 4 to 40 million, from Mach 0.3 to 0.9. Three homothetical profiles of NACA 0012 were also tested. Wind tunnel wall interferences were studied and recommendations on relative dimensions of models to test sections were made. In three dimensional flow, four homothetical models of a typical transport aircraft were tested in twelve transporic tunnels used for tests in various countries. The data were compared in a broad range of Raynolds number (0.3 to 7 million) between Mach number 0.7 and 0.96. Discrepancies can be reduced with corrections due to the free tunnel and wall interference. The effect of tripping the transition by grits was also analyzed, and comparisons were made with an axisymmetric body near Mach 1.

N76-28268 Aeronautical Research Inst. of Swaden, Bromma COMMENT ON RESULTS OBTAINED WITH THREE ONERA AIRPLANE CALIBRATION MODELS IN FFA TRANSONIC WITHOUTH TUNNELS

S. E. Gudmundson and S. E. Nyberg. In AGARD. Flight/Ground Testing Fac. Correlation. Apr. 1976. 7 p. refs. (For availability see. N78-25266.16-09)

Some test results are presented from three-component measurements for three of the ONERA Airplans Calibration Models (designated M1, M2, M3). The tests were performed in the FFA transonic wind tunnels HT, S4 and TVM 500 in the Mach number range 0.7 to 0.96 and at Reynolds numbers, based on the mean chord of the wing, in the range 0.2 to 1.0 million Comparisons are made for small angles of attack with results obtained with a small model (M1) in a large wind tunnel (ONERA S2MA in Modane). The agreement between the different tunnels is fairly good when the Reynolds number is the same. The Reynolds number effects are relatively large especially on the pitching moment in the lower Reynolds number range, which might mask some wind tunnel interference offects.

R A Kilgore and R E Kuhn In AGARD Flight/Ground Testing Fac Correlation Apr 1976 16 p refs (For availability see N76-25265 16 09) CSCL 148

A new fan-driven high Reynolds number transpinic cryogenic tunnel the National Transpinic Facility is being planned for the United States. This tunnel will provide an order of magnitude increase in Reynolds number capability over existing tunnels. Theoretical studies and experience with the Langley 1/3 Meter Transpinic Cryogenic Tunnel indicate that the cryogenic concept allows the attainment of full-scale Reynolds number at reasonable levels of dynamic pressure. The unique modes of operation which are available only in a cryogenic funnel make possible the separation of Mach number, Reynolds number possible the separation of Mach number, Reynolds number, and aeroelastic effects. By reducing the drive power requirements to a level

where a conventional fan drive system may be used, the cryogenic concept makes possible a tunnel with high productivity and run times sufficiently long to allow for all types of tests at reduced capital costs and, reduced total energy consumption

REYNOLDS NUMBER DATA CORRELATION STUDY N. S. Dougherty, Jr. In AGARD Flight/Ground Testing Fac Correlation Apr. 1976 7 p. Sponsored in part by NASA (For availability see: N76-25266-16-09)

A sharp, smooth, 10-deg included angle cone was tested on twenty-one major wind tunnels of the United States and Western Europe to obtain correlation data on the effect of acoustic disturbances in wind tunnel flow on boundary layer transition Reynolds number. The cone is planned to be flight tested in order to obtain a basis of reference for the wind tunnel data over a nominal range of Mach numbers from 0.4 to approximately 2.0. Wind tunnel data obtained over a Mach number range from 0.2 to 4.6 are broadly characterized according to wind tunnel test section geometry and, in turn, to the types of acoustic disturbances associated with the geometry

The NASA Langley Transonic Dynamics Tunnel, which has a variable density Freon-12 (or air) test medium, was designed for the study of dynamics and aeroelastic problems of serospace vehicles. During the 15 years of operation of this facility there have been various opportunities to compare wind tunnel and flight test results. Some of these opportunities arise from routine flight checks of the prototype, others from carefully designed comparative wind tunnel and flight experiments. Data obtained from various sources is presented. The topics covered are: gust and buffet response, control surface effectiveness, flutter, and active control of seroelastic effects. Some benefits and shortcomings of Freon-12 as a test medium are also discussed. Although areas of uncertainly are evident and there is a continuing need for improvements in model simulation and testing techniques. the results indicate that predictions from aeroelastic model tests are, in general, substantiated by full scale flight tests

SOME AEROELASTIC DISTORTION EFFECTS ON AIR-CRAFT AND WIND TUNNEL MODELS

G F Moss and D Pieros /n AGARD Flight/Ground Testing Fac Correlation Apr 1976 11 p refs (For availability see N76-25266 16-091

Aspects of the aeroelastic distortion of wings in flight and in the tunnel are disnussed. The effects of such distortion could be of prime importance when correlating flight and wind tunnel data, particularly when supercritical flows are present which tend to be comparatively sensitive to small geometric changes. It is suggested, that as transonic facilities operating at higher stagnation pressures come into more general use as a means of achieving higher Reynolds numbers, better means of making allowances for the aeroelastic distortion of wind tunnel models. will be necessary in flight the full benefits of advanced-wing technology will probably be achieved if similar improvements can be made to the techniques used by the aircraft designer. In the long term, methods need to be found to control and use aeroelastic distortion to enhance aerodynamic performance in flight. Reference is made experimental and theoretical data obtained with respect to these problems

PROBLEMS OF NOISE TESTING IN GROUND-BASED FACILITIES WITH FORWARD-SPEED SIMULATION John Williams in AGARD Flight/Ground Testing Fac. Correlation Apr 1976 14 p refs (For availability see N76-25266 16-09)

An overview of the design and operational problems associated with ground-based facilities for performing noise experiments with forward-speed simulation was presented. Various facilities were described it was concluded that it is unlikely that one type of facility will be able to cater effectively for the whole range of simulated flight aero-anoustic measurements needed in aircraft noise R and D studies, towards the evolution of quieter military and civil aircraft without operational or economic penalties. Modified wind-tunnel type facilities are seen as providing the best approach for noise-model research work. The role of aircraft flight experiments was described, with the application of carefully controlled flight experiments using research-oriented modifications of small aircraft. The functions of large low-speed tunnels in noise testing was described, in relation to the development and exploitation of small acoustic tunnels. Author

N76-25282 Deutsche Forschungs- und Versuchsanstalt führ tuft- und Raumfahrt, Brunswick (West Germany) STATUS OF METHODS FOR AIRCRAFT STATE AND PARAMETER IDENTIFICATION

P. G. Hamel In AGARD Flight/Ground Testing Fac Correlation Apr 1976 16 p refs (For availability see N76-25266 16-09)

The report of a meeting on aircraft system identification for flight test engineers and pilots, handling qualities and simulation experts, and aircraft and control system designers, was presented It was shown that in recent years several identification procedures have evolved for obtaining aircraft parameters from inflight measurements. These approaches have been shown to have good success for conventional (winged) aircraft and have become practical to apply. The parameter identification problem becomes a much more complicated task for large and slender body aircraft where the elastic deformations at high dynamic pressure can no longer be neglected. For helicopters, simplifying assumptions are also, in general, considerably more difficult due to the strong coupling of the rigid body degrees-of-freedom, because of the different flexible motions introduced by the rotor blades, and because of the shortness of the test period which can be recorded due to the inherent instability of these vehicles

Correlation Apr 1976 7 p refs (For availability see N76-25266 CSCL 01C

The results obtained so far with a remotely piloted research vehicle (RPRV) using a 3/8 scale model of an F-15 simplane, to determine the usofulness of the HPRV testing technique in high risk flight testing, including spin testing, were presented. The program showed that the RPRV technique, including the use of a digital control system, is a practical method for obtaining flight research data. The spin, stability, and control data obtained with the 3/8-scale model also showed that predictions based on wind-tunnel tests were generally reasonable

N76-25268 institut de Mecanique des Fluides de Lille (France) FLIGHT SIMULATION USING FREE-FLIGHT LABORATORY SCALE MODELS (SIMULATION DE VOL PAR MAQUETTES DE VOL LIBRE EN LABORATOIRES!

Jean Gobeltz. In AGARD. Flight/Ground Testing Fac. Correlation Apr 1978 16 p rets in FRENCH, ENGLISH summary (For availability see N76 25266 16-09)

Two operating procedures related to the laboratory testing of free-flight models are defined the direct similarity' teating where tests have to predict directly the results of the flight tests of the full scale arcraft, and the indirect similarity. Tusting where tests are used first for analysis of the phenomena, secondly for its modelling which is later applied to the arcraft itself. Dynamic stall and spin results are given as examples of 'direct similarity' testing. Use of indirect similarity' is shown to be a similarity' testing. Use of indirect similarity' is shown to be a broader and more scientifically fertile testing procedure. Examples quoted are relative to the longitudinal dynamic behavior and vertical atmospheric guist response of arcrafts. It is shown how for phenomena modelling, both stationary aerodynamic character sites and aerodynamic diminatives date of the model are extracted of purposely designed flights. Those data are their used for computation. Piloting muthods of the models are given. Other types of tests relative to fanding or cross wind landing, disching, transversal guists and active controls are also mentioned. Authority

COMMENTS ON WIND TUNNEL/FLIGHT COMPARIZONS AT HIGH ANGLES OF ATTACK BASED ON BAC ONE-ELEVEN AND VC10 EXPERIENCE

M.W. Salisbury. In AGARD Flight/Ground Testing Fac. Correlation. Apr. 1976. 4 p. (For availability see N76-25266-16-09)

The flight test and wind tunnel measuraments made at high incidence on the BAC 111 have been used to find the effects of Reynolds number and Mach number on the maximum value of the lift coefficient. It is shown that the effect of Mach number changes in the range 0.18 to 0.27 are of the same order as the effect of the Reynolds number change between wind tunnel and flight. The flight/tunnel comparison on the VCIO is used to show the importance of representing the geometry of the slat and wing profile in great detail in order to achieve a satisfactory correlation. Examples are also given of the type of modification which has to be made to wind tunnel data in order to achieve agreement between flight and simulator handling characteristics at the stell, and of the use of a simple and plate model to everygate the effect on drag of detail configuration changes.

N76-25291 Bell Helicopter Co., Fort Worth, Tex THE ART AND SCIENCE OF ROTARY WING DATA CORRELATION

Jan M Drees In AGARD Flight/Ground Testing Fac Correlation
Apr. 1976 11 p. refs (For availability see N76-25266 16-09)

An overview of the correlation of helicopter rotor performance and loads data from various tests and analyses was presented information is included from free-flight full-scale tests in a 40 x 80 wind tunnel, one-fifth scale tests in a Transonic Dynamic Tunnel, and small scale tests of a rotor in air. These test data are compared with each other, where appropriate, and with calculated results. Typical examples illustrate the state of the art for correlation and indicate anomalies encountered. It is concluded that a procedure using theoretical analyses to aid in interpretation and evaluation of test results is essential to developing a science of correlation.

COMPANISON OF MODEL AND FLIGHT TEST DATA FOR
AN AUGMENTOR-WING STOL RESEARCH AIRCRAFT

W. L. Cook and D. C. Whittley (De Havilland Aircraft Co., Ltd., Downsview, Ont.). In AGARD. Flight/Ground Tasting Fac. Correlation. Apr. 1976. 12 p. rels (For availability see N78-25268-18-09). CSCL 01C.

The major areas of confidence derived from wind tunnel tests performed on the Augmentor-Wing jet-STOL research aircraft were deliminated and it was shown that, for the most part, tunnel results compare favorably with flight experience. Since the model differs in some respects from the actual aircraft, precise correlation between tunnel and flight tests results were not expected, in some areas the model tests were known to be non representative so that a degree of uncertainty remained, these areas of greater uncertainty are identified and again discussed in the light of subsequent flight tests.

CORRELATION OF LOW SPEED WIND TUNNEL AND FLIGHT TEST DATA FOR V/ETOL AIRCRAFT

Woodrow L Cook and David H Hickey In AGARD Flight/Ground Testing Fac Correlation Apr 1976 10 p refs (For evailability see N75-25266 16-09)

CSCL OIC

The availability of wind tunnel test data for correlation purposes of the same V/STOL alreaft tested in flight is very limited. This is due in a large part to size limitations of wind tunnels and the number of wind tunnels available for testing of full-scale aircraft. Wind tunnel tests are described for two research aircraft - the XV-5B fan-in-wing sircraft and the YOV-10 RCF (rotating cylinder flap) aircraft - in the NASA Ames 40- by 80-foot wind tunnel. The tests were conducted specifically to provide for correlation between wind tunnel and in-flight serodynamics and noise test date. Correlation between serodynamic and noise data are presented and testing techniques that are related to the accuracy of the data, or that might affect the correlations, are discussed. The correlation of noise measurements made with a J-85 engine mounted on a F 108 sircraft during low altitude flyovers with the same J 85 engine mounted on a model and tested in the Ames 40- by 80-foot wind turinel are also reported

N76-25294 Royal Aircraft Establishment, Bedford (England)
A BRIEF FLIGHT-TUNNEL COMPARISON FOR THE
HUNTING H 126 JET FLAP AIRCRAFT

D. N. Foster In AGARD Flight/Glound Testing Fac. Correlation Apr. 1976 7 p. refs (For availability see N76-25266 16-09)

Flight measurements of the variation of lift with angle of incidence, for an airorah with an internal-flow jet flap, were compared with results deduced from wind-tulnial tests of the aircraft itself, and of a one-seventh scale model of the aircraft. The correlation is shown to be unsatisfactory for large flap deflection and high values of the jet momentum. The effects of the wind-tunnel wall corrections, and of some uncertainties in the position error correction, were investigated in order to suggest areas where further work could lead to improvements in the flight-tunnel correlation.

N76-28286 Royal Alteraft Establishment, Bedford (England). FLIGHT MEASUREMENTS OF THE LONGITUDINAL AEMODYNAMIC CHARACTERISTICS OF A VECTORED THRUST AIRCRAFT (HS-P1127) THROUGHOUT THE TRANSITION

C. J. Thorpe and A. A. Woodfield /n AGARD Flight/Ground Testing Fac Correlation Apr 1976 21 p refs (For availability see N76-25265 16-09)

At low speeds, the serodynamic force and moment coefficients on a vectored thrust jet V/STOL aircraft are primarily functions of the three variables - incidence angle, thrust deflection angle and the ratio of free stream to jet momentum per unit area leffective valocity ratio). To obtain an indication of the influence of each variable and obtain data requiring a minimum of correlation for comparison with model results, quasi-static non-equilibrium flight test techniques were developed. The principles underlying serodynamic lift, drag and pitching moment measurements on jet V/STOL aircraft are examined. Test and analysis procedures used for flight tests on the P1127 prototype at the RAE are described. Examples of results from the flight tests are used to illustrate the various test techniques.

EFFECTS OF SUFFETING AND OTHER TRANSONIC PHENOMENA

William E. Lemar In AGARD Flight/Ground Testing Fac. Correlation Apr. 1976-32 p. refs (For availability see N76-25266 16-09)

Buffeting and other transonic phenomiena are viewed in the context of highly maneuvering fighter aircraft. The fighter combat problem is first discussed from the viewpoint of the pilot with emphasis on the effects of buffeting and stability and control problems which occur during highly maneuvering flight. The current state of knowledge and available data relating to the tolerance and performance of the pilot in this flight regime is then reviewed to sum up the assessment of buffeting effects on piloting capabilities. Basic transonic flow separation phenomena, structural dynamics, and relevant aspects of flight control are viewed from the standpoint of the technologists to provide understanding of the hasic effects. Various aspects of buffeting are reviewed to aircraft design and development, and means of improving aircraft design to reduce buffeting and flight control problems. The situation regarding correlation of ground, wind tunnel and flight tests is reviewed and the need of improvements in such correlations is noted. Gaps in capabilities and needs for research and development are given emphasis

SWEDISH EXPERIENCE ON CORRELATIONS OF FLIGHT RESULTS WITH GROUND TEST PREDICTIONS

Svein Teige, Gunner Straeng, and Kerl-Erik Staeke. In AGARD Flight/Ground Testing Fac. Correlation. Apr. 1978. 10 p. ref. (For availability see N78-25266 15-09)

Some of the wind tunnel data and flight test data obtained during the development work on the SAAB 37 Viggen aircraft are compared. Three different areas of testing were selected (1) spin tests, (2) injet tests and (3) measurements of aerodynamic derivatives. The main spinning and recovery characteristics of the aircraft are in good agreement with those predicted from wind tunnel tests, one exception being that the inverted spin mode has not been found in flight tests. Generally, the agreement between uncorrected inlet scale model tests and full scale is fair, but with a tendency of model flow measurements to be a conservative prediction of the aircraft performance. By correcting the model data for Reynolds number effects and probe sizing influence, an almost perfect correlation was achieved. The

serodynamic derivatives measured in flight tests are in good agreement with data predicted from wind tunnel tests and calculations. No important Reynolds number effects have been found.

N76-25300 Hawker Siddeley Aviation Ltd., Brough (England) FLIGHT/TUNNEL COMPARISON OF THE INSTALLED DRAG OF WING MOUNTED STORES

A J Grundy In AGARD Flight/Ground Testing Fac Correlation Apr 1976 16 p. refs (For availability see N76-25266 16-09)

installed drags for a range of stores mounted on the outboard wing pylon (mid semi span) of a Hawker Siddaley Buccaneer S. Mk 2 were measured in full scale flight and on a 1/12th scale wind tunnel full model. This minal comparison covers several types of stores including a simple tank, a rocket pod and twin side-by-side carriage of fron bombs up to 0.88 Mach number. The flight results were obtained using quasi-steady flight test techniques; excess thrust was detived from triple-exis accelerometer measurements and thrust from an altitude test facility, engine final nozzle calibration using jet pipe pressure. The comparison of incremental drag shows that agreement is satisfactory. Clean stores show good agreement but 'dirty' stores generally have lower drag in flight. Data on changes in lift and pitching moment are also presented.

COMMENTS ON MATHEMATICAL MODELLING OF EXTERNAL STORE RELEASE TRAJECTORIES INCLUDING COMMARISON WITH FLIGHT DATA

G. A. Cox and K. Carr. In AGARD. Flight/Ground Testing Fac. Correlation. Apr. 1976. 19 p (For availability see N76.25268. 16:09)

The ability to reproduce wind tunnel and flight store jettison trajectories using a mathematical modelling technique is demonstrated A correlation is shown between flight trajectories and predictions using mathematical models incorporating data from (1) matching of wind tunnel jettisons with corrections to full scale conditions (2) wind tunnel measurements of installed store loads and store free-air serodynamic forces and moments. The potential of the mathematical modelling technique to minimize wind tunnel and flight store jettison programs is demonstrated.

The problems of comparing results obtained from wind tunnels with those derived from actual flight tests were discussed it was pointed out that corrections must be made to relate these results directly, due to aercelastic effects and the effect of Reynold's number differences. For instance, high aerodynamic loads may alter significantly the general aerodynamic shape of aircraft as compared to that of the corresponding scale models, corrections must then be made to the coefficients measured with wind tunnels, making predictions more difficult in addition, certain problems arise in the measurement of aerodynamic coefficients over the transcribe regime. Using results obtained with the Airbus and Concorde aircraft, an attempt was made to point out the accuracy that may be expected from aerodynamic

A method is described for human engineering assessment of avionic systems. The method is based on the use of human inspiniering criteria for which examples are given. The way these criteria lead to system evaluation and system optimization is shown by examples.

N76-29290 Centre d'Essais en Vol. Istres (France) INVESTIGATION OF THE LANDING APPROACHES FOR A STOL AIRCRAFT USING A FLICHT SIMULATOR [ETUDE AU SIMULATEUR DU PILOTAGE D'UN AVION STOL EN APPROCHE]

J P Petit and J C Raynal (ONERA, Modane) In AGARD Flight Simulation/Guidance Systems Simulation Jun 1976-15 p. In FRENCH ENGLISH summary (For availability see N76-29287 20-09)

The influence of instrumentation in the establishment of longitudinal handling qualities orderia for approach and flare was investigated. Velocity vector head-up display, IFR and VFR instrumentation were tested. Various types of STOL aircraft wore defined by modification of the engine thrust static and dynamic characteristics and by modification of the lift coefficients, in order to give them various flight path margins and various flight path rates of change. The simulation methods used to define several STOL aircraft, the test program conducted, and the results obtained are described.

THE USE OF A FLIGHT SIMULATOR IN THE SYNTHESIS AND EVALUATION OF NEW COMMAND CONTROL CONCEPTS

R Onken, V Adam, and R Dierke In AGARD Flight Simulation/Guidance Systems Simulation Jun 1976 16 p. refs (For availability see N76:29287-20:09)

The introduction of digital electric flight control systems as well as new theoretical techniques in optimal control open new ways in overall design. In particular, the development of advanced command control systems offers great promise. A flight simulator is used as a design old and as a means for exploratory and

comparative investigations for the study of flight path command systems. Some results show the tracking performance achieved with an optimized control law and suitably modified pilot interfaces.

USE OF THE FLIGHT SIMULATOR IN YC-14 DESIGN
Robert E. Spitzer In AGARD Flight Simulation/Guidance Systems
Simulation Jun. 1976 14 p. refs (For availability see N76-29287
20-09)

The twin-engine USAF/Boeing YC-14 STOL prototype is approaching the final stages of fabrication and assembly. With upper-surface-blowing powered lift, and triplex digital flight control system, the YC-14 represents a new generation of transport strongt. The piloted flight simulator has served as an integral tool in the design process. The flight simulation work that supported and guided YC-14 development is described. Organization and features of the digital math model are discussed The simulation includes powered-lift effects, engine bleed for leading edge BLC, mechanical and electrical flight control systems. serial delivery modes, and a newly developed wind and turbulence model. The three main contributions of the simulator are covered. criteria development, control system definition, and validation of flying qualities. Criteria for engine-out STOL approach are discussed. Control laws were developed for conventional piloting techniques for STOL speed and flight path control Satisfactory flying qualities were validated by Boeing, USAF, and NASA pilots for a wide range of flight conditions. It is concluded that the flight simulator is an invaluable tool in the design of advanced technology aircraft such as the YC-14

A JOINT PILOT/LANDING OFFICER SIMULATION PER-FORMED TO DETERMINE AIRCRAFT WAVE-OFF PERFOR-MANCE REQUIREMENTS

Ronald L. Nave In AGARD Flight Simulation/Guidance Systems Simulation Jun. 1976 10 p. refs (For availability see N76-29287 20-09)

A combined pilot/landing signal officer simulation was performed at the Naval Air Development Center in order to develop requirements for the wave-off performance of Navai aircraft. The simulator was also used to investigate the dynamic interaction between the pilot and landing signal officer. Thrust/ weight ratio and wing loading were identified as being the most important aircraft parameters influencing wave-off performance. A wave-off performance requirement was developed which specified minimum values of aircraft normal acceleration as a function of trim airspeed and time after initiation of the wave-off maneuver A minimum thrust/weight ratio of .4 and a maximum power approach wing loading of 90 lb/sq ft were recommended based on pilot opinion gathered in the simulation. In a separate LSO experiment it was determined that the landing signal officer could detect aircraft altitude errors during approach as small as 5 feet at 1/4 mile range.

N76-29304 National Aerospace Lab , Amaterdam (Netherlands). DESIGN AND PERFORMANCE OF THE FOUR-DEGREE-OF-I REEDOM MOTION SYSTEM OF THE NLR RESEARCH FLIGHT SIMULATOR
W. P. Koovermans and C. J. Jansen /// AGARD Flight

W. P. Roovermans and C. J. Jansen // AGARD Flight Simulation/Guklance Systems Simulation Jun 1876 11 p (For availability see N76-29287 20-09)

The motion system of the NRL research flight simulator with freedom of motion in heave. Oil, pitch and yaw is described To give good motion cues, smooth operation without any jerks is required. To this end specific hydraulic jacks were developed in which stick-slip phenomena are eliminated by introducing nytriostatic bearing between the moving piston and rod and the fixed cylinder, resulting in an acceleration threshold level below 0.01 g. A mathematical model was prepared to simulate and study the behavior of the hydraulic jacks. Results are given of measurements on single jacks and the complete system.

comprising acceleration noise and threshold level, dynamic response and performance diagrams. Because of the required oil pressure for the hydrostatic bearing, special procedures have to be followed to start and stop the operation of the system A description is given of the principles of the safety system applied.

N76-29305 Crambold Inst. of Tochnology (England). Dopt. of Electronic and Control Engineering FEEL FORCE BYSTEM WITH AN INERTIA REDUCTION

J. M. Lipscombe and D. J. G. Lewis. In AGARD. Flight Simulation/Guidance Systems Simulation. Jun. 1976. 13 p. lefs (For availability see: N76-29287-20-09).

CAPABILITY

The design, construction, and test of a single and twin stick feel force system is described. The systems have the usual variable feel characteristics of stiffness, damping, backlash, Coulomb friction and breakout force, and also a variable inertia, so that the effective inertia can be increased to more than the stick inertia, or reduced to a small proportion of the stick inertia. Parameter plane design techniques are applied to a high order mathematical model of the system, and a digital computer and visual display unit are used in interactive mode, to evaluate and plot the locus of the parameters of the system for any desired pole and zero locations on the s-plane. The performance of the model is then compared to the performance of the system under test.

N76-29306 Royal Aircraft Establishment, Bedford (England) Flight Systems Dept DEVELOPMENTS IN THE BIMULATION OF ATMOSPHERIC TURBULENCE

B. N. Tomilinson. In AGARD. Flight Simulation/Guidance Systems. Simulation. Jun. 1976. 14 p. refs (For availability see N76-29287 20-09).

In ground-based simulation of stretaft flight, inclusion of atmospheric turbulence is essential to the successful evaluation of handling and ride qualities, and to the greation of a realistic subjective environment and representative pilot workload. A new model of atmospheric turbulence capable of generating timehistories which reproduce the essential discrete-gust and non-Gaussian features of turbulence is described. A principal aim of the model is to reproduce the quality of intermittency identified in real atmospherio turbulence from the non-Gaussian distributions of velocity differences. Qualitatively, intermittency appears in a turbulence record as relatively isolated large changes in gust velocity embedded in a background of low activity. Compensor with flight measurements of atmospheric turbulence shows that power spectra, intermittency, and discrete gust content are accurately reproduced by the model A parameter in the model enables intermittency to be controlled explicitly and matched to a variety of weather conditions and terrain. Experiments in a simulator have shown acceptance by pilots, but cradible simulation of turbulence and its effects requires a high quality motion system. The model exists as a FORTRAN computer program and as an analogue hardware device Although orginally concerned with 'pilot-in-the-loop' simulation, the model of turbulence described has relevance and application in other areas, such as certification trials of automatic landing equip-

SIMULATION OF PATCHY ATMOSPHERIC TURBULENCE, BASED ON MEASUREMENTS OF ACTUAL TURBULENCE G. A. J VanDeMoesdijk In AGARD Flight Simulation/Guidance Systems Simulation Jun. 1976 14 p. refs (For availability see N76-26287 20-09)

Pilot dissatisfaction with the characteristics of Gaussian simulated turbulence in flight simulation stimulated a research program to determine the relevant non-Gaussian aspects of actual atmospheric turbulence needed in a realistic turbulence simulation. A model describing the so-called patchy characteristics of atmospheric turbulence as sensed by the pilot is developed in which the degree of patchiness is defined in mathematical terms. Results of actual measurements of patchy characteristics analyzed in a method indicated by the model are compared to the model characteristics. Finally a digital simulation of real-time patchy turbulence velocities is presented.

ANALYSIS OF AIR-TO-AIR MISSILE REQUIREMENTS AND WEAPONS SYSTEMS EFFECTIVENESS IN AN AIR-COMBAT MANEUVERING ENVIRONMENT

D L Gleseking, J. H Simpson, and J. W. Oestreich (NWC) In AGARD Flight Simulation/Guidance Systems Simulation Jun. 1976 9 p (For availability see N75-29267 20-09)

A simulation developed to aid in air-to-air missile system requirements analysis, missile subsystem design, and weapon system effectiveness is described. The air combat analysis (ACA) simulation was developed in support of advanced Navy air-to-air missile programs to offer improved design techniques for use with highly effective missiles. The ACA simulation brings added realism into the design process by introducing the combat environment as an independent input into the simulation. The combat environment is introduced by using mock combat aircraft trajectories (hassle) or manned cockpit simulation trajectories as initial conditions for missile firings. To illustrate the capability of the ACA simulation, sample analyses are discussed which demonstrate requirements analysis, subsystem design, and weapon system affectiveness. The preprocessing of the aircraft hassle data and the initialization of the missile simulation, the detail involved in the simulation itself, and the postprocessing of the simulation data to give intercept performance, failure summary, and terminal geometry, are described

N76-29311 McDonnell Aircraft Co., St. Louis, Mc. APPLICATION OF MANNED AIR COMBAT SIMULATION IN THE DEVELOPMENT OF FLIGHT CONTROL REQUIRE-MENTS FOR WEAPON DELIVERY

J. B. Berger, R. P. Mayer, and David L. Carleton (AFFDL) In AGARD Flight Simulation/Guldance Systems Simulation Jun. 1976 20 p. refs (For availability see N75-29287 20-09) (Contract P33615-73-C-3122)

Manned air combat simulations were conducted to develop requirements for tautical advanced aircraft/waspon systems in which precision tracking and weapon delivery are optimized through flight control system design. The objectives were to (1) develop analytical pilot models that relate weapon delivery accuracy to the ontire integrated aircraft/displays/sight/geometry system for air-to-air and air-to-ground weapon delivery tasks. (2) validate and incorporate these pilot models into the

Terminal Agrial Weapon Delivery Simulation (IAWDS) digital computer program, and (3) use the TAWDS program to determine how aircraft flying qualities affect air to air gunnery, and air-to-ground gunnery and bombing weapon delivery effectiveness The TAWDS program enables a digital simulation to be performed on various closed loop weapon delivery systems under manual tracking control for predicting and evaluating weapon delivery accuracy. Tracking performance results, acquired from analytical pilot simulations, are compared with those obtained from the manned simulations, and the Tactical Weapon Delivery (TWeaD) flight test development programs. These results indicate that the judicious use of the all digital analytical weapon delivery program in completion with manned simulation studies provides a very cost effective approach in designing, developing, and optimizing advanced enerall/weapon delivery systems. The evaluation of flying qualities for piloted advanced aircraft. performing air-to-ground weapon delivery tasks in terms of weapon system affectivaness, is shown to be feasible for determining and establishing flight control requirements

N76-29312 Litton Systems, Inc. Woodland Hills, Cant. DEVELOPMENT OF A SYSTEM FOR SCORING SIMULATED BOMBING RUNS

J. S. Ausman and F. J. Hellings (6585th Test Group). In AGARD Flight Simulation/Guidance Systems Simulation. Jun. 1976 19 p. ref (For availability see N76-29287-20-09).

A Bomb Scoring System (BSS) to be used in evaluating radar bombing capabilities of F-111 and AG alteratives developed. The BSS consists of an inertial navigation system updated with practision range and range-rate measurements to a set of 2 to 4 ground transponders placed in close proximity to the target A pod contains the girbonic equipment (inertial navigation system and range/range-rate interrogator) and attaches to a standard weapon station on the alteraft White the alteraft makes its (simulated) bombing run, the BSS pod continually monitors its position and velocity relative to the target. The alteraft's weapon delivery system sends its release pulse to the weapon station which holds the BSS pod Subsequently, the computer predicts where the bomb would have landed if one had actually been released. Bomb impacts and other pertinent data are stored in memory for immediate readout when the airplane returns to base.

WASI: WEAPON AIMING TRAINING SIMULATOR

Uwe Schulz In AGARD Flight Simulation/Guidance Systems Simulation Jun 1976 10 p (For availability see N76-29287 20-09)

An inflight training system for the squadron training of pilots is defined. The system provides realistic training in ground attack with simulated bombs, consons, and rockets on a range or in tactical settings without the restrictions normally imposed by safety considerations, shortage of training armmunition, lack of availability of live firing ranges, etc. The system is self-contained within a standard modified drop-tank (WASI-POD), with the absolute minimum of mechanical and electrical interfaces. It provides an immediate indication to the pilot of miss distance and direction, while the most important parameters of the action are recorded on tape for subsequent play-back and analysis on the ground equipment. The WASI is suitable for basic training. refresher training, as well as continuous realistic tectical training. A detailed description of the system is given including some aspects concerning the future applications in the training for the air air firing and dog fights.

N76-29314 Royal Netherlands Air Force, The Hague, PROFICIENCY TRAINING OF PILOTS AND CONTROLLERS PARTICIPATING IN RNLAF MISSIONS BY THE USE OF A SIMULATOR

J Alwon In AGARD Flight Simulation/Guidance Systems Simulation Jun. 1978 4 p (For availability see N76-29287 20-09)

Simultaneous training of pilots and mission controllers by coupling a ground-based simulator with a radar control center is reported. The flight training simulator is briefly described. Results of pilot training and mission controller simulation are given.

ON THE FLOW QUALITY NECESSARY FOR THE LARGE EUROPEAN HIGH-REYNOLDS-NUMBER TRANSONIC WINDTUNNEL LEHRT

J. P. Hartzulker (National Aero- and Astronautical Res. Inst., Amsterdam), P. G. Pugh (Royal Altoralt Estab., Bedford, Engl.), W. Lorenz-Meyer (DFVLR, Goettingen, Germany), G. E. Fasso (ONERA, Chatillon sous Bagneux, France), and D. Kuechemann, ed. (Royal Aircraft Estab., Famborough, Engl.) Mar. 1978. 31 p. refs.

(AGARD-R-644; ISBN-92-835-1214-6) Avail: NTIS HC A03/MF A01

The Large European High Reynolds Number Transonic Windtunnel (LEHRT) is meant to provide serodynamic data at high Reynolds numbers of high standard in a relatively short running time (dictated by economic reasons). This implies that the flow quality in LEHRT has to be excellent. Quantitative requirements for turbulence level as well as for pressure fluctuations have been developed in this report.

CONSTITUTION OF THE ATMOSPHERE IN THE GAS TURBINE

In Its High Temperature Corrosion of Aerospace Alloys 1975 p 37-39 (For avrilability see N76-11244 02-23)

A typical marine dissel fuel was burned in the turbine. The SO3/SO2 ratio as a function of the fuel-to-air ratio (FAR) is shown; the air injet temperature to the combustor was assumed to be 800 F. The equilibrium flame temperature, as a function of the FAR, for air inlet temperatures of 400 to 600 F is shown. The equilibrium composition of the flame gas, as a function of the FAR, is given. Actual analyses of the turbine exhausts indicated that the SO3 content was much less than that expected. The relative distribution of sulphur and sodium among their species as a function of temperature for the gas conditions is given.

N76-11248 Advisory Group for Aerospace Research and Development, Paris (France).

VAPOR PRESSURE AND CONDENSATION OF SODIUM BULPHATE

In its High Temperature Corrosion of Aerospace Alloys refs (For availability see N76-11244 02-23)

The corrosion deposits of sodium sulphate that occur on gas turbine metal alloy parts were studied. The chemical reactions occurring during high temperature corrosion are examined, and results are given for chemical analyses of various alloy specimens which were exposed to synthetic see salt concentrations. Also included are diffusion data for various alloy combinations and the methods used to study high temperature corrosion for each alloy combination. The diffusing elements for different metallic oxides are also given.

N76-11249 Advisory Group for Aerospace Research and

Development, Paris (France). OXIDATION AND HOT CORROSION OF COMMERCIAL SUPERALLOYS

In its High Temperature Corrosion of Aerospace Alloys 1975 p 117-482 refs (For availability see N76-11244 02-23) A summary of information on the oxidation and corrosion of 52 commercial nickel and cobait base superalloys is presented. The composition of each alloy is given. The effects of the comburtion of various sulphur-containing fuels and salt spray on alloy corrosion is examined. The results of weight analyses and chemical analyses of oxidized alloys are given. Photomterographs of hot corrosion on turbine blades are shown Results of thermal cycling tests are given

N76-11250 Advisory Group for Agrospace Research and Davelonment, Paris (France).

THE REFRACTORY METALS In its High Temperature Corrosion of Aerospace Alloys

1975 p 463-602 refs (For availability see N76-11244 02-23) The oxidation rates of the refractory metals, tantalum. niobium, molybdenum, and tungsten are examined. The composition of alloys of these metals is listed. The resistance of the alloys to exidation at different temperatures, exygen pressures, and time exposures is given. Weight changes, color changes,

oxide scale thicknesses, and some mechanical properties of the alloys are given. The exidation resistance of various alloy combinations is examined. The physical and chemical properties of molybdates are listed.

REQUIREMENTS FOR AND CHARACTERISTICS DEMAND-ED OF HIGH TEMPERATURE GAS TURBINE COMPO-NENTS

L. P. Jahnke and C. A. Bruch In AGARD Specialists Meeting on Directionally Solidified In-Situ Composites Aug. 1974 p. 3-12 refs (For availability see N75-11034-02-24)

Composite structures consisting of high strength fibers or plates in ductile matrices with outstanding high temperature properties are achievable in directionally solidified euteotics. This new class of materials represents a major innovation in gas turbine blade technology. The advantages and limitations of the two more promising euteotic systems and the relationship of these properties to turbine blade design is discussed. Innovations in design and further property improvements will be required to successfully exploit these materials in engine hardware. It is concluded that the payoff offered by this technology fully justifies a major investment of resources to achieve a practical system.

THE STRUCTURE AND THERMAL STABILITY OF EUTEUTIC ALLOYS.

G. C Weatherly In AGARD Specialists Meeting on Directionally Solidified In-Situ Composites Aug. 1974 p 13-20 refs (For availability see N75-11034-02-24)

The factors that control the as-grown morphology, crystallography and thermal stability of uni-directionally solidified eutectic alloys are briefly reviewed. The crystallographic orientation relationships that are usually found in UDG alloys are considered only in their bearing on the thermal stability problem. The stability of rood morphologies and the possible coarsening mechanisms in faulted and perfect arrays of parallel roofs are discussed for the extreme cases of diffusion and interface-controlled reactions. The coarsening mechanisms in tamellar euteotics are simpler and are controlled by the faults grown in during sollidification. The roles of tamellar terminations, sub-grains and discontinuous coarsening at migrating grain boundaries are considered. Finally, the problems encountered in phase stability of carbide reinforced nickel based superalloys during that hot tensile deformation, are reviewed.

THE MECHANICAL METALLURGY OF DIRECTIONALLY SOLIDIFIED COMPOSITES: STRENGTHENING FUNDA-MENTALS, TENSILE, CREEP, FATIGUE AND TOUGHNESS PROPERTIES

Alan Lawley In AGARD Specialists Meeting on Directionally Solidified in Situ Composites Aug. 1974 p 21-33 refs Sponsored by the Navy (For availability see N75-11034 02-24)

A fundamental basis for the interpretation and prediction of the mechanical behavior of in-situ composites is developed by considering possible strengthening mechanisms and associated models. Experimental property data and structural observations are then discussed in light of these mechanisms. The general features of tensile, creep, fatigue, and impact loading are characterized and behavior interpreted from the viewpoint of structure. Where possible, observed and predicted response of in-situ composites are compared, as is the behavior of comparable synthetic composites. The various structure-machanical property correlations allow for a rationalization of the major advantages

and disadvantages of in-situ composites vis a vis synthetic composites and other advanced structural materials. Author

EUTECTIC PHASE EQUILIBRIA

E. Blank In AGARD Specialists Meeting Directionally Solidified In-Situ Composites Aug. 1974 p 81-92 refs (For availability see N75-11034 02-24)

Computational and experimental paths to the determination of phase diagrams are discussed which are not in common use computer calculation, use of directional solidification, and use of diffusion techniques. Computer calculation of phase diagrams at present is confined to ternary systems. Although calculated phase boundaries often agree well with experimental values, the influence of the metallic solution models on the calculated results is not well understood. Generally, thermochemical data of the limiting binary systems are sufficient for the calculation of the ternary diagram. Ternary phases cannot be predicted a priori. Usually, they are limited to lines of specific stotchiometry. To lower costs computation should be carried out by a few specialists. - Experimentally, the influence of all alloying elements on the shape of the liquidus and solidios surfaces may be sillowed for by a directional solidification techniques. Some diffusion techniques appropriate to solid state reactions are elucidated. Author

PROSPECT OF DIRECTIONALLY SOLIDIFIED EUTECTIC SUPEHALLOYS

Herve Bibring In AGARD Specialists Meeting on Directionally Solidified In-Situ Composites Aug. 1974 p 141-155 refs In FRENCH; ENGLISH summary (For availability see N75-11034 02-24)

An evaluation was made of the possibilities offered by the utilization of more fully developed high temperature DS composites as aircraft blade materials. Two families of these materials are emphasized, namely: the famellar intermetallic eutectics of the Ni3Al-Ni3Nb type recently broadened to the quaternary composition systems Co/Ni3Al-Ni3Nb with Cr additions, and the COTAC family of multicomponent fiber composites whose complex superalloy matrices are reinforced by in-situ aligned monocarbide whiskers. When compared to the best present day superalloys, both these families show an important gain in operational temperatures. Weak points, particularly noticeable in some of these new materials, such as lack of ductility poor corrosion resistance, and thermal cycling problems should be improved.

SPECIALISTS MEETING ON FAILURE MODES OF COM-POSITE MATERIALS WITH ORGANIC MATRICES AND THEIR CONSEQUENCES ON DESIGN

Mer. 1975 162 p refs in ENGLISH; partly in FRENCH Presented

at 39th Meeting of the Struct and Mater Panel, Munich, 13-19 Oct. 1974

(AGARD-CP-163) Avail NTIS HC \$6.25

The aerospace industry's constant search for structural materials which offer advantages of high strength, low density. high fatigue endurance and adaptability to the intended function, is reported. The understanding of the failure mechanism of an isotropic material like a metal, where fracture is essentially a single parameter problem, is still a difficult subject, but the quantitative analysis of the failure of anisotropic composites, where many parameters are involved, becomes infinitely more complex Time conference proceedings contains the text of twelve papers given at the AGARD Specialists Meeting organized to consider the problem. The latest developments in the study of failure of composite materials is contained in these papers. Included are analyses of the failure modes of these materials and presentation of methods to predict such failures. Included also are methodol ogy and equipment for studying failures of composite materials, methods of testing composites to detect incipient failures, and suggestions of design criteria for the use of composites in order to achieve a safe-life design procedure for structures and components constructed of fiber-reinforced composite materials For individual titles, see N75-23699 through N75-23710

PREDICTION OF STATIC AND FATIGUE DAMAGE AND CRACK PROPAGATION IN COMPOSITE MATERIALS

M J. Owen and P T Bishop In AGARD Specialists Meeting on Fishure Modes of Composite Mater With Organic Matrices and Their Consequences on Design Mar 1975 12 p refs (For availability see N75-23698 15-24)

Finite element stress analysis was used to predict the stresses around a hole in finite width plates febricated from various glass-fiber reinforced plastics. The results were used to predict the initiation of damage at holes under static and fatigue loading and showed that they act as almost fully effective stress concentrators. This approach leaves a number of important problems unsolved. Firstly, for some materials there appears to be a substantial adverse size effect. Secondly, in the life range from 1,000 to 1 million cycles the fatigue curve is nearly straight and attempts to extrapolate to long lives lead to the prediction of zero safe stress amplitude at finite lives. Thirdly, the onset of transverse fiber damage is often an unacceptably severe criterion. Preliminary work on two of the GRP materials has shown that size effects can be represented through a fracture toughness approach and the problems of extrapolation to long lives and damage tolerance can be doalt with by means of a crack growth law (1) based on stress intensity factor range.

N78-23700 Washington Univ., St. Louis, Mo. FAILURE CRITERIA TO FRACTURE MODE ANALYSIS OF COMPOSITE LAMINATES

Edward M. Wu in AGARD Specialists Meeting on Failure Modes of Composite Mater With Organic Matrices and Their Consequences on Design Mar. 1975 11 p refs (For availability see N75-23698 15-24) (Contract F33616-72-C-1514; Grant AF-AFOSR-74-2687)

Quantitative understanding of the paremeters which control composite fracture is imperative to the implementation of fall safe design and inspection of critical load bearing structures. For isotropic materials, fracture is essentially controlled by a single parameter, e.g., the fracture toughness or the stress intensity factor. This one dimensional nature lends itself to experimental quantification. However, for anisotropic composites there are at least seven primary controlling parameters. (1) crack length; (2) orack orientation with respect to material axis of aniantropy. (3) nature of applied combined stresses, (4) lamination geometry. (5) deformational and strength responses of the constituent lamina. (6) three kinematically admissible modes of crack extension and (7) crack trajectory. Because of this large number of parameters, experimental quantification by systematic permutation of the parameters must be realistically viewed as intractable. This paper presents an analytical method of reducing these parameters from seven to two and furnishes experimental observations which lend support to the theoretical model

N75-23701 Deutsche Forschungs- und Versuchsanstalt füer Luft- und Raumfahrt, Stuttgart (West Germany)

AN EXPERIMENTAL STUDY TO DETERMINE FAILURE ENVELOPE OF COMPOSITE MATERIALS WITH TUBULAR SPECIMENS UNDER COMBINED LOADS AND COMPAR-ISON BEYWEEN SEVERAL CLASSICAL CRITERIA

U Huetter, H Schelling, and H Krauss In AGARD Specialists Meeting on Failure Modes of Composite Matter With Organic Matrices and Their Consequences on Design Mar 1975 11 p refs (For svallability see N75-23698 15-24)

For conventional isotropic materials failure hypotheses are known, which yield comparative failure stresses for combined load conditions. Such failure hypotheses may be described in three-dimensional failure envelopes, both, experimentally and analytically. For fiber-reinforced composites, with the defined layerwise orthotropy of elestical and mechanical properties, a number of analytical approaches to failure hypotheses are known in order to determine these failure envelopes of fiber reinforced materials experimentally, a testing equipment was set up. Using tubular specimens it was possible to find out the critical failure limits under general in-plane stress. This report describes the installations required, the testing schedule, manufacturing and structural design of the specimens as well as the results found by extensive series of experiments. These results are compared with theoretical values of failure hypotheses available. Author

PRACTICAL FINITE ELEMENT METHOD OF FAILURE PREDICTION FOR COMPOSITE MATERIAL STRUCTURES E. Henze and S. Roth. In AGARD. Specialists Menting on Failure Modes of Composite Mater. With Organic Matrices and Their Consequences on Design. Mar. 1975. 11 p. refs. (For availability see N75-23698 15-24).

A dimensioning procedure for anisotropic structures with the same resources already used to calculate and measure isotropic structures is examined. The available means of calculation and measurements are the finite element method and the strain gage technique. The recessory input data for the finite element method are: the elastic constants of the unidirectional lamina, the fiber orientation to a basic system and the contents of the different layers, characterized by the elastic constants and fiber angle, in the whole laminate. The output of the used finite element program are the streases in each lamina of the whole laminate in any structure. These stresses are compared in a failure criteria with maximum stresses measured by simple test specimens. The comparison of calculation and tests of several different specimens, using the procedure described, are presented.

STRESS AND STRENGTH ANALYSIS OF REINFORCED PLASTIC WITH HOLES. CONSEQUENCES ON DESIGN J. Wiedemann. H. Griese, and M. Glahn /n AGARD Specialists Meeting on Failure Modes of Composite Mater. With Organic Matrices and Their Consequences on Design Mer. 1975 11 p. refs (For availability see N75-23698 15-24)

Composites with outcuts strain distributions in biaxial reinforced specimens were measured and calculated according to the elastic theory. The tangential stress at the edge was compared with the orthotropic strength of the material. Thus failure position and ultimate load could be estimated. To improve strength, various possibilities are proposed: around holes, the woven reinforcement can be widered without cutting fibers, medium sized holes can be reinforced by patches, large outcuts should be shaped in a neutralizing way and stiffened by rovings. If patches are applied, failure occurs at the hole or in front of the patch or by delaminating. Patches with elliptical shape prove advantageous for unidirectional loading according to theoretical and empirical investigations. In case of blastial loading, a round neutralizing patch can be recommunded. With respect to this case, calculations were made for icotropic and orthotropic materials. Also shear stiffness and stress of the adhesive are considered.

FRACTURE BEHAVIOUR AND RESIDUAL STRENGTH OF CARBON FIBRE COMPOSITES SUSJECTED TO IMPACT LOADS

G. Dirrey In AGARD Specialists Meeting on Failure Models of Composite Muter: With Organic Matrices and Their Consequences on Design Mar. 1975 12 p. refs (For availability see N75-23898 18-24)

Carbon liber reinforced plastic (CFRP) has properties such as high specific strength and stiffness which are attractive for

aerospace applications. However, it can be susceptible to impact damage at relatively low incident energies. Brittle fibers in a brittle matrix can absorb appreciable amounts of energy only by fracture processes. This paper describes a variety of such fracture processes by which CFRP laminates can fail under impact conditions. Which failure mode occurs in a particular situation is discussed in terms of material properties, component geometry and the kind of loading. Of particular interest to the designer are residual strengths and stiffnesses after impact and typical are illustrated for CFRP laminates subjected to dropweight and ball our impact, from subcritical energies up to complete penetration. Material modifications, simed at minimizing certain types of impact damage are described and examples given, such as hybrid composites and modified fiber arrangements, which show promise of improved impact resistance. OPTICAL METHODS FOR TESTING COMPOSITE MATERI-

I. M. Daniel In AGARD Specialists Meeting on Failure Modes of Composite Mater. With Organic Matrices and Their Consequences on Design Mar. 1975 20 p. refs (For availability see N75-23698 15-24)

Optical stress analysis techniques and their application to the study of deformation and fracture of composite materials are described and discussed. These include photoelastic coatings. moire grids, holographic interferometry, and liquid crystals. Photoelastic coatings are used to determine full-field surface strain distributions, strain concentrations around gracks and other discontinuities, and initiation, mode and propagation of fracture. Moire techniques yield full-field displacement and strain distributions. They have been applied to the detection of crack propagation and its associated failure modes, the determination of strain concentrations and the study of the interlaminar shear edge effect. The sensitivity of the method can be greatly enhanced by using frings multiplication techniques. Holographic interferometry is most suitable for determining out-of-plane deformations. It is particularly useful in the study of flexure of plates, modes and amplitudes of vibration, and failure modes resulting in out-of-plane deformstions, such as delaminations. The high sensitivity of liquid crystals to heat and their property of emitting visible radiation make them suitable for detecting local delaminations and fatigue fractures. All these techniques have different advantages and limitations. The selection of any one or more of these depends on each particular application.

DESIGN OF COMPOSITE STRUCTURE WITH RESPECT TO AVOID CRACK PROPAGATION

K Brunsche In AGARD Specialists Meeting on Failure Modes of Composite Mater. With Organic Matrices and Their Consequences on Design Mar. 1975 9 p. ref (For availability see N75-23698 15-24)

Within the manifold of composite structures developed, rotary wings are the best known components. Several types of composite rotorbisdes have been developed, tested, and produced. The experience with fatigue testing many GFP, CFP and mixed modulus coupons and full scale blade sections is used to make some design recommendation how crack propagation might be avoided. Respect is given to both influence of fabrication and influence of environment. For some cases deformation limits up to which no damage propagation occurs are given.

CONSIDERATION OF FAILURE MODES IN THE DESIGN OF COMPOSITE STRUCTURES

L. B. Greszczuk In AGARD Specialists Meeting on Failure Modes of Composite Mater. With Organic Matrices and Their Consequences on Design Mar. 1975 24 p. refs (For svailability see N75-23698 15-24)

(Contracts N00019-72-C-0221, N00019-73-C-0405)

Pertinent equations are presented for predicting, from the properties of constituents and composite microstructure, the strength of unidirectional composites subjected to tensile, compressive, and shear loading in the fiber and transverse directions, the latter being normal to the fiber axis. Influence of fiber and matrix properties, voids, and ineffective or unbonded fibers on the strength and failure modes of composites are discussed. Typical examples are given on the application of results to the design of composite laminates and structures including-sensitivity of properties of multilayer, multidirectional composites to the aforementioned failure modes; reshaping of cultout shapes in composite plates to minimize the dependance of the plate's strength on a given material strength parameter; use of hybrid multiphase composites to improve strength properties and performance; and use of composite-reinforced metals for buckling critical applications and others.

GENERATION OF COMPOSITE MATERIAL DATA FOR
DESIGN

I. C. Taig. In AGARD. Design of Struct, in Composite Mater (Basic Data and Interdisciplinary Action). Jan. 1976. p. 1-7 (For availability see N78-19235-10-34).

Quality control in the manufacturing of fiber composites (laminates) used in aircraft construction is discussed. Specifically considered is the availability of technical information on the mechanical and thermal properties of laminates. The availability of this information is presented in tabular form A rating scale (lettered A to E) serves as a key to the tables and indicates wither extensive technical information (i.e. letter A) or minimal technical information (i.e., letter E). Exposure of laminates to the manufacturing environment (e.g., humidity, solvents) is also considered. It is proposed that the burdensome requirement that every primary composite has its own development program can be eliminated if components are built in standardized ways from a finite family of layups using previously developed structural elements.

24 COMPOSITE MATERIALS

The serospace industry in the United States has made significant strides in the development of advanced composite technology, for primary as well as for secondary structural applications. This technology has advanced to the point where the feasibility of using these materials is no longer questioned. Unfortunately, applications which can reap the benefits of the technology have not developed as fast as they should, since improvements in technical (know-how) education, and experience are required in a number of areas. One such area is the interface. between the design engineer and the materials engineer. The significance of the design engineering/materials engineering interface in the development of advanced structures is examined. To achieve a smooth-working design/materials interface. long-term emphasis in three specific areas is suggested: (1) education (on the industrial level and also bank to the colleges and universities). (2) interdisciplinary development of advanced composites, and (3) development of composites test standards.

(AGARD-CP-184-Paper-II-2) Avail NTIS HC 53 50

The exact equations of turbulent, chemically reacting flow were used, together with an order of magnitude analysis, to derive an approximate form of the turbulence kinetic energy balance equation for premixed, two-dimensional, turbulent flames at low Mach number and high Reynolds number. Plausible closure hypotheses were then introduced, in order to obtain an equation which reduces to a familiar form of the turbulence kinetic energy equation, in the case of nonreacting flow of constant density Additional terms, related to heat release and mass transport, become important in turbulent flames. Experimentally observed effects of turbulence on a variety of turbulent flame configurations are discussed in terms of this equation.

DESIGN OF ALUMINUM ALLOYS FOR HIGH TOUGHNESS AND HIGH FATIGUE STRENGTH

J. G. Kaufman, In AGARD. Specialists Meeting on Alloy Design for Fatigue and Fracture Resistance Jan 1976 26 p refs (For availability sue N73 19268 10-26)

The basic concepts employed in designing fracture-resistent aluminum alloys are reviewed, and specific examples of the application of these concepts are presented in detail. The importance of consideration of strength and stress-corrosion resistance in addition to toughness and fatigue strength is emphasized, and it is pointed out that most successful applications of alloy design techniques have been in the areas of toughness and stress corrosion resistance, with little commercial success in the area of fatigue. The roles of interfaces and of various sizes and types of particles in initiating and propagating cracks is examined, and the steps necessary to control the size and specing of insoluble constituents and precipitates as well as the grain morphology are discussed. Outstanding examples of the application of microstructural control are sluminum alloys 2048. 2124, 2419, 7050 and 7475, and the specific approaches to their development as well as data illustrating the commercial success are presented. Of the group, 7475 represents the optimum available in the toughness regime, while 7050 provides the best combination of strength, toughness and stress-corrosion resistance of the commercial alloys. METALLURGICAL ASPECTS OF FATIGUE AND FRACTURE IN TITANIUM ALLOYS
C A Stubbington In AGARD Specialists Meeting on Alloy

Design for Fatigue and Fracture Resistance Jan. 1976 19 p refs (For availability see N76-19268 10-26)

The basic features of alpha-beta titanium allovs which result in property anisotropy are the elastic and plastic anistropy of the haxagonal alpha phase, and the sensitivity of their microstruc-tures to thermomechanical processing. Mechanisms of fatigue crack initiation and microstructural requirements for resistance to initiation are discussed. The effect of drystallography on fatigue crack growth is described, and the apparent conflict in microstructural requirements for resistance to fatigue crack initiation and resistance to fatigue crack growth is indicated. It is concluded that in future work, microstructure and texture should be considered simultaneously in rolation to fatigue properties, rather than separately, as has largely been the case hitherto. The relationships between microstructure, interstitial content and toughness in titanium alloys are discussed, and the importance of crystallography is highlighted. It is suggested that optimization and control of microstructure, interstitial content, and texture will be required for maximum toughness, and for maximum resistance to stress corrosion and sustained load cracking in alpha-bets alloys it is also suggested that the approach to the texture parameter could either be to randomize it by heat treatment, or to control it and take advantage of the tough orientations. Maximum directional toughness will be obtained by a combination of microstructural optimization and textural toughening

THE THEORY, SIGNIFICANCE AND PREVENTION OF CORROBION IN AIRCRAFT

Sep 1976 158 p refs Presented as a lecture series. Wright-Patterson AFB, Ohio. 6-7 Oct. 1976, Delft, Netherlands, 11-12 Oct. 1976, Lisbon, 14-15 Oct. 1976 (AGARD-LS-B4) Avail NTIS HC \$6.75

The significance, implications and economics of the various types of corrosion in aircraft were discussed, as well as the threats and preventive measures for the product life cycle, design, material selection, construction, maintenance and repair, inspection and test. The stress is placed on the need for greater application of known preventive methods, greater visibility of the problem, expanded engineering education, and better practical transfer of knowledge and technology. For individual titles, see N76-33333 through N79-33340.

N76-33333 Promisel (N. E.), Silver Spring, Md. INTRODUCTION: A SURVEY OF THE PROBLEM

N E. Promisel In AGARD The Theory, Significance and Prevent. of Corrosion in Aircraft Sep. 1976 5 p (For availability sea N76-33332 24-26)

The overall situation and perspective of the corrosion problems in aircraft was reviewed. A striking paradox is that, despite extensive research and knowledge in the field of corrosion and practical invesures to combat it, aircraft corrosion damage is still being experienced that annually is costing many millions of dollars, as well as indirect penalities such as aborted missions, decreased aircraft usage factor, and even, occasionally, safety hazards to aircraft and personnel. It appears that there does not exist an adequate transfer of technology between scientists,

engineers, designers, and users. The cost of corrosion should be determined by looking at a complete life cycle of a total system. Aucraft are subject to practically every type of corrosion pitting, intergranular, fatigue, stress-corrosion cracking, crevice, bacterial, embrittlement, fretting, galvanic, etc. Easy access for in situ inspection should be a prime factor in aircraft design.

N78-33334 Tachnische Hogeschool, Delft (Netherlands) CORROSION THEORY AND PRACTICE

W A Schultze In AGARD The Theory, Significance and Prevent of Corrosion in Aircraft Sep. 1976 19 p. refs (For availability see N76-33332 24-26)

A number of basic concepts and definitions related to corrosion were first reviewed, such as metallic corrusion, electrolytic corrosion, electrochemical reaction, electrode reaction. The thermodynamical concept of the equilibrium electrode potential was then introduced and applied to the various types of eleutrode reactions that could occur between metal and environment. The kinetic concepts of polarization and overpotential are treated and applied to the study of the rate of the reactions that are involved in corrosion processes. This is followed by a discussion of the mixed potential theory of electrochemical corrosion for a homogeneous metal. Some aspects of the types of corrosion that can occur when a metal consists of different phases, a combination of different metals is used, or a metal structure is exposed to an inhomogeneous environment or to stresses, are presented; these include pitting corrosion, crevice corrosion, intergranular corrosion, stress corrosion gracking, or corrosion

N76-33335 Ohio State Univ., Columbus. Dept. of Metallurgical Engineering.

ECONOMICS OF CORROSION

R W. Staehle In AGARD The Theory, Significance and Prevent. of Corrosion in Aircreft Sep. 1976 3 p (For availability see N76-33332 24-26)

The uncertainties related to the problems of defining the real costs of corrosion to military situated due to the complete lack of manipulable information were described. Valious information that informal estimates suggest that the costs directly associated with corrosion, including lepair and inspection, are at least 25% of the maintenance costs, which are of the order of \$1.5-2.0 billion per year. Some general considerations which should serve as a reasonable basis for improving the understanding of not only corrosion economics but the general problem of maintenance sconomics are outlined.

N76-33336 Naval Aircraft Materials Lab.. Fleetlands (England). CORROSION IN AIRFRAMES, POWER PLANTS AND ASSOCIATED AIRCRAFT EQUIPMENT

E.J. Hammersley In AGARD. The Theory, Significance and Prevent of Corrosion in Aircraft. Sep. 1976. 16 p. refs. (For availability see N76-33332 24-26).

A review of corrosion problems in airframes, power plants, and aircraft equipment primarily found on neval and other aircraft operating in marine environments was presented. The following factors affecting the problem were first discussed exposure (special nature of marine environment), initial standards (choice of materials, protection and inspection techniques, maintenance), economics (original cost and operating cost), awareness of the problem (training of uners). Specific corrosion problems encountered in the following aircraft components were then described airframe structures (aluminum, magnesium, ferrous, titanium alloys; paint protective systems, geometric considerations, and the use of temporary or supplementary preservatives), engines, and aircraft equipment. Some comments on corrosion monitoring were also given.

CORROSION: STUDY AND DETECTION

M. Brunin, G. Sertour, and C. Bezaud In AGARD The Theory, Significance and Prevent of Corrosion in Alroraft Sep. 1976 16 p. refs (For availability see N76-33332 24-26)

Two lines of approach to the study of corrosion phenomena are examined in parallel: corrosion reproduction and accelerated tests, and determination of corrosion rates. (1) Accierated Corrosion Tests. Various types of test have been developed for the reproduction and acceleration of natural phenomena, such as salt spray, continuous and elternating immersion, and climatic gygle tests, together with exposure to marine and tropical environmental conditions. The development and utilization of these tests by a series of exemples is demonstrated. (2) Measurement of Corrosion Rates. The rate of corrosion is obviously a valuable tool for forecasting damage resulting from this phenomenon, and its measurement is therefore amply justified. Methods used in this context, in particular the use of potentiostatic curves and measurement of impedance at low frequencies, are described. The application of these methods to the testing of snudizing is illustrated. In the context of stress corrosion gracking, the study of the kinetics of crack propagation likewise represents a powerful method of investigation and forecasting.

N76-33339 Ohio State Univ. Columbus. Dept. of Metallurgical Engineering

DESIGNING FOR CORROSION PREVENTION

R W. Staehle In AGARD. The Theory, Significance and Prevent. of Corrosion in Aircraft. Sep. 1976, 26 p. refs (For evallability see N78-33332 24-26)

Approaches that may be used in aircraft design to prevent or minimize, in general, corrosion were discussed. These include: (1) simple preventive ideas, such as avoiding chlorides, high surface stresses, hydrogen in metals, etc., (2) point of view that aircraft must be designed on the basis of cyclic loading or fatigue, (3) the life cycle costs (capital and maintenance) must be kept as low as possible without compromising safety, reliability, or availability, (4) compromise must be made between the use of high strength, light weight, heterogeneous material systems and the chemical or mechanical instability of all engineering materials, with resulting problems of accelerated corrosion due to intimate juxtaposition. Applications were made to the 8-1 program and to various allovs

TRENDS IN THE APPLICATION OF ADVANCED POWDER METALLURGY IN THE AEROSPACE INDUSTRY

G. P. Peterson In AGARD Advan. Fabric. Tech. in Powder Met. and Their Econ. Implications Nov. 1976 9 p (For primary document see N77-15152 06-26) Avail: NTIS HC A11/MF A01

A variety of jet propulsion and sirframe components were examined in terms of cost factors, it is shown that the dominant factor in increasing costs is metal removal or maghining. Powder metallurgy is proposed as a means of reducing the costs of machining engine and aircraft components. Hot isostatic pressing, rotating electrode process, press and sinter, and extrusion are among the processes discussed.

The titanium alloy powder made by the rotating electrode process consists of closely-sized, high purity spherical particles within the range of 50-800 micrometers. Although earlier REP powders had been produced by a technique employing a tungsten cathode, this source of contamination was eliminated as a result of process modifications which make use of titanium cathodes, in either a consumable or nonconsumable mode

H. Stephan In AGARD Advan. Fabric. Tech. in Powder Met. and Their Econ. Implications Nov. 1976 6 p (For primary document see N77-15162 08-26) Avail: NTIS HC A11/MF A01

Manufacturing of metal powders, especially of titanium and nickel-super-alloys of highest purity in the most aconor, ical way is discussed. The powder can be of 100% spherical shape and of 50 - 800 micron diameter and of flake size of 20 - 400 mesh or a mixture of both. High purity is achieved by processing in high vacuum, melting with the piogrammed electron beam and atomizing with a water-gooled rotating disk. This allows reduction of hydrogen from TI-slipys and reduction of C. O2, H2 and N2 from Ni-super-alloys and avoids contamination of the metal powder from the environment, the heat source and the atomizing system.

TITANIUM POWDER PRODUCTION BY THE HARWELL
CENTRIFUGAL SHOT CASTING PROCESS
P. W. Sutcliffe and P. H. Morton (Imperial Metal Ind. (Kynoch).
Ltd., Birmingham, Engl.) In AGARD Advan Fabric. Tech. in Powder Met, and Their Econ, Implications Nov. 1976 4 p refs (For primary document see N77-18152 08-25) AVall: NTIS HC A11/MF A01

The centrifugal shot casting (CSC) process, which has particular relevance to the production of titanium alloy powders is briefly described. The process is one of several centrifugal stumization techniques being developed throughout the world which incorporates the mechanism of disintegration of molten titanium into discrete droplets. The melting of a titanium alloy electrode and the subsequent atomization as it takes place in the CSC process is illustrated. In addition, calculations of the time taken for pure titanium dioplets of 50-500 micrometers diameter to solidify in flight are presented, as well as the distances traversed during solidification. The dependence of these parameters upon the nature and pressure of the inert gas environment is considered.

PERFORMANCE AND ECONOMICS OF HIP EQUIPMENT IN INDUSTRIAL USES

Hans T. Larker In AGARD Advan, Fabrio, Tech. in Powder Met. and Their Econ. Implications Nov. 1976 8 p (For primary document see N77-15152 06-26) Avail: NTIS HC A11/MF A01

þ

Hot isostatic pressing (HIP) is an established process within some segments of industry and emple experience has been gained from the use of ASEA QUINTUS(R) HIP equipment in production, both cold loaded for cemented carbide products and hot loaded for high speed tool steel. A design for the insulation system of HIP furnaces invented about ten years ago and then further developed has proven to give high reliability and low maintenance cost. Examples of HIP processing costs for a cold loaded unit and a hot loaded pressing line are given. The calculated costs ranging from some tens of cents to about a dollar per kg material being treated should enable a rapidly increasing use of the HIP process.

One area of application has received more attention than any other, this being turbine disks where the requirement is not for the ultimate in high temperature resistance but for optimized mechanical properties at intermediate temperatures. These components land themselves ideally to manufacture by the powder route since nearly all the advantages of powders over conventional routes can be utilized. An integrated prowder production and compaction plant was installed simed at the commercialization of this type of component. Work on the forging of disks from hot isostatically pressed (HiP) billet is reviewed along with indications of the potential for other techniques applicable to the production of powder disks, i.e. preforms plus forging, direct HIP to shape, isothermal forging, thermoplastic processing.

The use of powder metallurgy to produce components from difficult-to-forge alloys was demonstrated. However, as the costs of raw materials, labor, and processing increase rapidly, the stimulus for continued powder processing development shifts from performance to that of rew material conservation and cost reduction. It was the object of this program to demonstrate the reproducibility of the product obtained from the forging of annular preforms using a carbon modified Astrology powder and to establish production processes and specifications relevant to this product. The technical approach taken was to produce hot isostatically pressed low carbon Astrology forging preforms from two powder sources. One source utilized high pressure consolidation, the other low pressure consolidation. These as-HIP'ad preforms were hammer forged. Subsequent mechanical property evaluation verified the quality of these components and a disk for engine qualification was made available for testing.

ADVANCEMENTS IN SUPERALLOY POWDER PRODUC-TION AND CONSOLIDATION

Louis J. Fledler In AGARD Advan, Fabric, Tech. In Powder Met. and Their Econ. Implications Nov. 1976 9 p (For primary document see N77-15152 06-26) Avail: NTIS HC 411/MF A01

A program was initiated to reduce the cost of fabricating superalloy turbine angine components through the utilization and improvement of powder metallurgical techniques. To date, investigations were conducted on both powder production and powder consolidation. Specifically, it was demonstrated that the cost of powder production could be significantly reduced at the expense of small property changes through the use of virgin materials and powder revert during metring, minimizing inert handling, and the use of coarser mesh fractions. Relative to consolidation, it was also shown that ceramic moids can be used to produce near net shaped parts by direct HIP or by sinter plus HIP schniques. The verification of these processes is currently in progress through the fabrication and evaluation of a full scale turbine disk with an integral stub shaft. Author

ISO-FORGING OF POWDER METALLURGY SUPERALLOYS FOR ADVANCED TURBINE ENGINE APPLICATIONS

M. M. Allen In AGARD Advan, Fabric, Tech, in Powder Met, and Their Econ. Implications Nov, 1976 15 p (For primary document see N77-15152 06-26) Avail: NTIS HC A11/MF A01

The Gatorizing forging process is a hot die isothermal technique used to produce complex configurations. This process utilizes the superplastic behavior imparted to advanced supersitory through prior processing and/or controlled forging parameters. This technique is currently being used in the production of all of the turbine disks and many of the compressor disks used in the FTOO engine program. The Catorizing technique has allowed production of a diverse array of precision forged net and near net shape supersitory components. Because the process uses hot dies and relatively low forming rates, the response of the as-Gatorized workpiece to subsequent heat treatment is remarkably uniform. Finally the Gatorizing process offers strong economic advantages over conventional forming techniques in applications which use expensive raw materials, require maximum material properties, or require complex component configuration.

METAL POWDER PRODUCTION BY VACUUM ATOMIZA-TION

J. M. Wentzell In AGARD Advan, Fabric, Tech, in Powder Met, and Their Econ. Implications Nov. 1976 6 p (For primary document see N77-16162 08-26) Avail: NTIS HC A11/MF A01

The potential energy for atomization can be stored within the motitan metal, which increases the efficiency. Also, the higher tap densities of vacuum-stomized powders, as compared with argon-atomized powders, is a distinct advantage. Alloy powders based on Ni, Co, Fe, Ci, Al, and misch metal were made successfully by this process. Powder metallurgy will play a dignificant role in this era of conservation and cost reduction, and vacuum atomization has shown that the unconventional approach may offer the most practical solutions to some of our current problems.

INVESTIGATIONS FOR MANUFACTURING TURBINE DISCS OF NI-BASE SUPERALLOYS BY POWDER METAL-LURGY METHODS

W. Betz, H. Huff, W. Track, M. Brandis, F. Schubert, and W. Spyrs. In AGARD. Advan. Fabric. Tech. in Powder Met. and Their Econ. Implications. Nov. 1976. 19 p. (For primary document see N77-15182 05-26).

Avail: NTIS HC A11/MF A01

The potential advantages arising from powder metallurgical production of turbine disks using different processing methods are discussed. Research work included the following production methods: (1) powder compressed by hot extrusion, disk shaping by forging in a conventional forging press: (2) Argon-atomized powder compressed by hot isostatic pressing (HIP), disk shaping by forging in a conventional forging press; and (3) Argon-stomized powder, compression and simultaneous disk shaping by HiP. The influence of different steps is discussed, e.g. HIP. parameters, folying parameters and heat treatments on microstructure and results of tensile tests (from RT up to 800 C), creep rupture test (650 C and 730 C), and low cycle fatique tests (test bars at RT and 600 C and spinned disks at RT). Parameters were found for HIP in combination with thermomechanical post treatment which produce a microatructure in which the previous particle grain boundaries are not densely covered by carbides. This microstructure leads to mechanical and technological properties which appear to to be adequate for the use of these PH-materials for turbine disks.

The possibility of obtaining high strength levels at intermediate temperatures in experimental cobalt-base alloys prepared by powder metallurgy (P/M) techniques was investigated. The first part of the work concerned P/M grades containing in wt%) 10 to 18%Ni, 20%Cr, 10%Mo and up to 1.8%C, strengthened mainly by solid solution effects and precipitation of carbides. The second part dealt with P/M grades containing lin wt%) 16%Cr, 3 to 5%Mo, 5%Ti and less than 0.1%C s.rengthened by solid solution affects and precipitation of the ordered fic.d. gamma-Co3Ti intermetallic compound. Prealloyed powders sizing less than 500 microns were prepared by N2 atomization and, for some of the Ti-containing grades, by the rotating electrode process After consolidation by hot extrusion of canned pow-ders, the alloys were hot worked by rolling or swaging and subjected to a final uging treatment. Ultimate tensile strengths up to 1850 MN/sq. m at room temperature and 1350 MN/sq. m at 850 C (1200 F) were obtained in the gernma-Co3Ti strengthaned alloys. Relationships between microstructures and mechanical properties are discussed in terms of the powder characteristics, and the extrusion and subsequent hot working and aging conditions. Author

COMPARATIVE EVALUATION OF FORGED TI-SAI-4V BAR MADE FROM SHOT PRODUCED BY THE REP AND CAC PROCESSES

R. F. Vaughan, P. A. Blankinson, and P. H. Morton, In AGARD Advan, Fabric, Tech. in Powder Met, and Their Econ. Implications Nov. 1976 7 p refs (For primary document see N77-15152 06-28)

Avail: NYIS HC A11/MF A01

Ti-6Al-4V shot was obtained from two sources, the centrifugal shot casting process and the rotating electrode process. The chemistry and size distribution of the two types of shot were compared prior to an evaluation of the consolidated products Alloy shot billets were produced by hot isostatic pressing (HIP) and the mechanical properties of as-HIP and as-HIP + forged/rolled material were compared. The two types of shot behaved in a similar manner and generally produced microstructures, tensile and fracture toughness properties similar to dest and wrought material. However, the low cycle fatigue behavior of the consolidated material was inferior to that observed in the conventional product. Internal fatigue origins were found to be associated with defects in the shot and in general the degree of scatter was higher and fatigue atrengths were lower than in conventional material of a similar section size.

Methods of design for improving the reliability of ceramics in structural applications are described. Based on the science of fracture mechanics, these methods provide a rational basis for estimating the lifetime of structural components that are subjected to applied loads. Data obtained by standard strength or fracture mechanics techniques are used to develop design diagrams from which component performance is evaluated. Three types of diagrams are described, depending on whether the critical flaw size in a component is estimated by nondestructive evaluation, proof testing, or statistical evaluation. The validity of the theory was tested experimentally, and, on the whole, agreement between theory and experiment is satisfactory. However, additional experimentation is suggested to fully evaluate the limits

document see N77-11185 02-28)

Avail. NTIS HC A06/MF A01

Ballistic properties of the conventional German light artillery rocket LAR I are described. The ratio of minimum to maximum range must be smaller to meet military requirements in second generation systems. A solid propellant rocket motor having two propulsive charges and two independent thrust periods of equal thrust levels is proposed. The charges are ignited in sequence by an electronic timing circuit at a predetermined time of delay for optimum thrust for maximum range

THE MEASUREMENT OF IGNITER HEAT FLUX IN SOLID

PROPELLANT ROCKET MOTORS

I. E. Smith and K. M. Siddiqui /n AGARD Small Solid Propellant
Rockets for Field Use Sep. 1976 13 p refs (For primary
document see N77-11185 02-28) Avail: NTIS HC A08/MF A01

Using platinum thin film gauges, the temporal and axial distribution of heat flux was measured from two different types of igniter compositions and two different igniter geometries. The parameters used were different igniter masses, tube langths, and nozzle throat diameters. The size distribution of the particulate matter arising from combustion of pyrotechnic materiels was investigated. Whereas radiation plays an insignificant part in the total heat transfer process, the 'point' heat flux due to particulate heat transfer was found to be an important mode of heat transport during joniter action.

While stored at various temperatures between 65 C and 90 C, several double base propellants with the same composition, differing only in the stabilizer, were aged artificially to the onset of autocatalytic decomposition. A correlation between the temperature and the storage period was established for the results obtained at the respective temperatures. The continuing aging of the propellant gives rise to stabilizer reaction products which are characteristic of the respective aging condition. These reaction products may be used as a criterion for different stages of aging within the shelf life of solid propellants.

N75-22487# Advisory Group for Aerospace Research and Development, Paris (France) SPECIALISTS MEETING ON FRETTING IN AIRCRAFT SVSTEMS

Jan. 1975, 229 p. rafs. In ENGLISH, partly in FRENCH Presented at 39th Meeting of the Struct and Mater 28th 1, Munich, 6-12 Oct 1974

(AGARD-CP-181) Avail. NTIS HC \$7.50

The effects of fretting and wear on the minute of aircraft structures and engines are examined. Various consist curisces are categorized in terms of their role in the maintenance of flight profile and structural integrity along with several typical fretting situations. The occurrence of fretting on the fan, dompressor, and turbine blades of jet engines is examined to include the effects on splines, rolling elements, bearing races, and secondary sealing elements of face type seals. The sequence of events which constitute the fretting mechanism is analyzed. For individual titles, see N75-22488 through N75-22503.

J. R. Lee In AGARD Specialists Meeting on Fretting in Aircraft Systems Jan. 1975 10 p (For availability see N75-22487

The fretting problem in helicopters which is created by the high frequency of alternating loads is discussed. Examples are given of some of the more common cases of fretting. The most serious effect of fretting is stated to be reduction in fatigue strength. Mathods for alleviating fretting by clamping pressure to prevent relative movement, improved jubilication, soft low strength interlayers, and hard wear resistant coatings are proposed. The author states that in many cases the only method for oliminating or reducing fretting is to redesign the component.

PHYSICS AND METALLURGY OF FRETTING

R B. Waterhouse // AGARD Specialists Meeting on Fretting in Aircraft Systems Jan. 1975 17 p refs Sponsored by Min. of Def. and Sci. Ren. Council (For availability see N75-22487 14-31)

Fretting corrosion and fretting fatigue are concerned with the oscillatory tangential relative movement of two contacting surfaces. In many contacts movement occurs over only part of the contact and fatigue cracks are frequently observed originating in the boundary between the slip and non-slip regions. Temperature rises in the contact zone can lead to the moelectric effects between dissimilar metals but these are less important than metallurgical effects, particularly in heat-treatable materials. Work-hardened and age-hardened alloys are particularly susceptible to fretting damage. The volume of material affected by the stress system is of importance in fratting fatigue.

N75-22496 Metasinstitut TNO, Apeldoorn (Notherlands). SURFACE DISTRESS OF COPPER ALLOYS IN CONTACT WITH STEEL UNDER FRETTING CONDITIONS

A. Begulinger and A. W. J. DeGee in AGARD Specialists Meeting on Fretting in Aircraft Systems. Jan. 1975. 10 p. refs. (For availability see: N75-22487. 14-31)

Study of the fretting behavior of copper alloys against steel showed that, in the presence of a liquid lubricant, the wear process is purely adhesive by nature. Tests, performed under conditions of continuous lubricated sliding, show that such tests may be used to provide a first rough estimate of the behavior of materials under conditions of lubricated fretting, provided that the rate of energy production under sliding conditions equals that under fretting conditions. In the absence of a lubricant the

process is determined exclusively by the formation and subsequent behavior of oxides on the steel surface. Now, tests performed under conditions of continuous sliding give no indication whatever of the behavior of materials under fretting conditions.

DESIGN OF PIVOTS FOR MINIMUM PRETTING

M. B. Peterson and F. F. Ling. In AGARD. Specialists Meeting. on Fretting in Aircraft Systems Jan. 1975 22 p refs (For ovallability see N75-22487 14-31)

An analytical and experimental investigation has been conducted on the fretting of pivots. A test rig was set up which allowed fretting studies to be conducted under a wide range of conditions of frequency, load, amplitude, temperature, time, materials and geometries. It was found that rolling contacts performed much more satisfactorily than sliding contacts because of limited microslip. Dynamic loads, gross silding, and changing of the contact area increase fretting substantially. Open contact geometries are less damage prone than more restrictive ones. Materials like tool steels and carbides are affective over a wide range of conditions when the interestin is limited. Designs are based on those contacts which give microslips less than 00004 in, and pressures less than 220,000 psi since these performed satisfactorily under long term tests. Since, microslips can be unlocated for any given materials and designs research is needed to determine microslip damage limits of various materials. In studying fretting, it is important to clearly understand the motions and the nature of the damage processes.

EFFECT OF VARIOUS MATERIAL PROPERTIES ON THE ADHESIVE STAGE OF FRETTING

Donald H. Buckley In AGARD Specialists Meeting on Fretting in Aircraft Systems Jan. 1976 19 p refs (For availability see N75-22487 14-311

Various properties of metals and alloys have been studied with respect to their effect on the Initial stage of the fretting process, namely adhesion. Crystallographic orientation, crystal structure, interfacial binding energies of dissimiliar motal, segregation of alloy constituents and the nature and structure of surface films have all been found to influence adhesion. High atomic density, low surface energy grain orientations exhibit lower adhesion than other orientations. Hexagonal metals in general manifest less adhesive wear than cubic metal. Knowledge of interfacial surface binding energies can assist in predicting adhesive transfer and wear. Selective surface segregation of alloy constituents can accomplish both a reduction in adhesion and improved surface oxidation characteristics. Equivalent surface coverages of various adsorbed species indicate that some are markedly more effective in inhibiting adhesion than others.

N75-22501 Flat S.p.A., Turin (Italy). SELF-LUBRICATING POLYMERS

Alfredo Franceschini In AGARD Specialists Meeting on Fretting in Aircraft Systems Jan. 1975 17 p. refs (For availability see N75-22487 14-311

Some polymers, either of the thermoplastic or the thermosetting type, are quite suitable as self-lubricating materials. Such bearings are useful whenever lubrication is impossible or impractical for temperature, weight, corrosion or other limitations. The most commonly used plastics in this field are the polytetrafluoroethylene, the polyamides, the polyacetals and the phenolics, these have been joined recently by a family of heat resistant materials, the polyimides. The significant material properties in tribulogy, in absence of lubrication, are the friction coefficient and the wear rate; to these are connected . In a more or less direct way - other physico-mechanical properties: thermal conductivity, hardness, and thermal expansion. With regard to running conditions the prominent parameters are temperature, load and sliding velocity; if they become more severe conventional polymers fall, and one must resort to more specialized materials. like PTFE sintered with bronze and lead, or members of a relatively new group of polymers: the polyimides

NUMERICAL ANALYSIS OF THE INFLAMMATION PHASE IN A TURBULENT MIXING BOUNDARY LAYER JANALYSE NUMERIQUE DE LA PHASE D'INFLAMMATION DANS UNE COUCHE DE MELANGE TURBULENTE)

Otto Leuchter In AGARO Anal. and Numerical Methods for invest of Flow Fields with Chem Reactions, Especially Related to Combust. May 1975 29 p. refs. In FRENCH, ENGLISH summary (For availability see: N75-30359 21-31)

A numerical description is given of the inflammation process in the turbulent mixing region between a fuel jet imixture of H2 and AR) and an external air stream, the two fluids being at the same temperature and of the same density. The initial conditions at the confluence are characterized by the velocity ratio and the initial boundary layer thicknesses. The description of the fields of mean quantities and second order correlations is performed by means of balance equations constructed from the general conservation theorems. Simplifying assumptions are introduced for the chemical kinetics, accounting for the particular behaviour of the hydrogen-oxygen chain reaction in the region of short ignition delay. The number of equations describing the chemical production and the effects of turbulence on it may thus be considerably reduced. The numerical solutions have revealed that the slowing effects of the turbulence are little affected by the initial conditions but depend essentially on the behaviour of the kinetics in the mixing layer, whenever the reduction of the inflammation length in the presence of boundary layers is due mainly to the distorsion of the mean velocity field A simple criterion for the inflammability of jets is established taking into account these results

Dept. of Applied N75-20264 California Univ., La Joila. Mechanics and Engineering Sciences
A REVIEW OF SOME THEORETICAL CONSIDERATIONS OF TURBULENY FLAME STRUCTURE

F A Williams In AGARD Anal. and Numerical Methods for Invest of Flow Fields with Chem Reactions, Especially Related to Combust May 1875 25 p (For availability see N75-30369 21.31)

The structure and motion of a laminar flame in a shear flow is considered. The atrain rate is established as a key turbulent-flow factor influencing flams structure it is concluded that promixed turbulent flames seldom are composed of an ensemble of sheared, premixed, laminer flames, while turbulent diffusion flames often are composed of a collection of faminar diffusion flames. A statistical description of premixed turbulent flame structure is outlined for turbulence of low intensity. The use of coupling functions is discussed for describing the structure of turbulent diffusion flames that consist of a statistical collection of faminar diffusion flames for which the flame-sheet approximation is applicable. It is shown how to obtain in a simple manner the average local volumetric production rate of nitric oxide in the turbulent diffusion flame, requiring as input only the local probability density function for the inert, evaluated at an inert concentration which corresponds to the flame-sheet position Author

KINETIC ENERGY OF TURBULENCE IN FLAMES
K. N. C. Bray In AGARD. Anal. and Numerical Methods for Invest of Flow Fields with Chem. Reactions, Especially Related to Combust May 1975 20 p refs (For availability see N75-30359 21.31)

The exact equations of turbulent, reacting flow are used, together with an order of magnitude analysis, to derive an approximate form of the turbulence kinetic energy balance equation for premixed, two-dimensional, turbulent flames at low Mach number and high Reynolds number Plausible closure hypotheses are then introduced, in order to obtain an equation which reduces to a familiar form of the turbulence kinetic energy equation, in the case of nonreacting flow of constant density. Additional terms, related to heat release and mass transport, become important in turbulent flames. Experimentally phaetyed effects of turbulence on a variety of turbulent flame configurations are discussed in terms of this equation.

A NUMERICAL SPECTROSCOPIC TECHNIQUE FOR ANALYZING COMBUSTOR FLOWFIELDS
Michael E. Neer In AGARD Anal. and Numerical Mathods for

Invest of Flow Fields with Chem Reactions, Especially Related to Combust. May 1975-22 p. rels (For availability see N75-30359 21.311

A computer program which calculates the ultraviolet emission and absorption spectra of OH is presented for use in conjunction with numerical programs which predict combustor flow field properties. Spatial distributions of OH number density and temperature, resulting from analytical flow field calculations, are used as input data for calculating the absolute intensities of the spectra. Of particular interest is the ability to calculate the shapes of the intensity envelopes associated with the low resolution slit settings of a given spectrometer. Comparisons are made with actual spectral data obtained with various degrees of spectral resolution. The computer program is also used to generate graphical inversion techniques for analyzing experimental spectra An example is given in which one such graphical technique is used to obtain average temperatures and number densities along the axis of an axisymmetric duct containing a supersonic diffusion flame Another example is presented to demonstrate the manner in which a second inversion technique can be used to obtain radial profiles of temperature and OH number density from radial scarning of an axisymmetric combustor flow field. Two cases involving thermodynamic nonequilibrium are also discussed, one of which involves a hot vibrational band and the other an electronic nonequilibrium

ANALYTICAL METHOD FOR PREDICTING CHEMICAL REACTION RATES IN THE PRESENCE OF INHOMOGENEOUS TURBULENCE (APPLICATION TO TURBULENT COMBUSTION) (METHODE ANALYTIQUE EN PRESENCE D'UNE TURBULENCE NON HOMOGENE (APPLICATION A LA COMBUSTION TURBULENTE))

Roland Borghi In AGARD Anal and Numerical Mathods for Invest of Flow Fields with Chem. Reactions, Especially Related to Combust May 1975 28 p refs in FRENCH, ENGLISH summary (For availability see N75-30359 21-31)

A theoretical approach to the reciprocal influence between turbulence and chemical reactions is presented. The approach is based on a conventional method for studying turbulence in inhomo-jeneous, monreactive flows, where the fluctuation evolution is followed and calculated by the evolution of their moments of order two. A quantitative calculation of the influence of turbulence on reaction rates is obtained by adding numerical calculation to analytical analysis.

N75-30368 California Univ., La Jolia. Dept of Applied Mechanics and Engineering Sciences STUDIES RELATED TO TURBULENT FLOWS INVOLVING FAST CHEMICAL REACTIONS

Paul A. Libby In AGARD Anal anti Numerical Methods for Invest. of Flow Fields with Chem. Reactions, Especially Related to Combust. May 1975–18 p. refs (For availability see N75-30359)

Turbulent flows involving chemical reactions in the simplest chemical system, fuel-oxidizer resulting in a single product are investigated. The conditions of the flow are assumed to be such that at a molecular level the reactions are infinitely fast. In this limiting case the properties of the turbulence determine the extent of chemical reaction. The physical picture of the chemical aspects of the flow which results from the assumption of fast chemistry and the experimental evidence to support this picture are emphasized. The mathematical consequences appropriate for the case of highly dilute reactions is then developed; it is shown that the crux of the problem of describing analytically the mean composition field resides in knowledge of rather detailed properties of a synthetic scalar quantity whose behavior can be related to that of a passive scalar in turbulent flows, for example, temperature or the concentration of helium in helium-air mixtures. In particular, It is shown that if at each point in the flow in question the probability density function of a synthetic scalar quantity is known, then the mean composition and the mean rate of creation of each species is determined. The results of calculations of a two-dimensional mixing layer with fuel in one stream and with oxidizer in the second stream are given. The results show the expected finite reaction zone.

CALCULATION OF THE EFFECT OF AFTERBURNING IN EXTERNAL SUPERSONIC FLOW BY MEANS OF A METHOD OF CHARACTERISTICS WITH HEAT ADDITION AND MIXING LAYER ANALYSIS

P. Mittelbach In AGARD Anal, and Numerical Methods for Invest of Flow Fields with Chem Reactions, Especially Related to Combust. May 1975-16 p. refs (For availability see N75-30359

A method is described for the calculation of the effect of afterburning in supersonic flow in the vicinity of a base body on the pressure distribution along this body. The basis for it is a method of characteristics, where the heat addition is prescribed. information on the distribution of heat sources is gained by an analysis of the turbulent leacting mixing layer applying the Patankar/Spalding boundary layer program. Examples showing the usefulness of this approach are given.

INJECTION FLOW FIELDS

John S. Evans and Griffin Y. Anderson In AGARD Anal. and Numerical Methods for livest of Flow Fields with Chem. Reactions, Especially Related to Combust. May 1976. 8 p. refs (for evaluability see N75-30369 21-31)

Adequate prediction techniques for supersonic, mixing, reacting flows are of great importance in the design and performance analysis of supersonic combustion ramjet (scramjet) engines. Analytical programs for parallel injection flow fields with chemical reaction and turbulent mixing are now svallable for both single and multiple-jet flows. The application of these analyses to simple flow geometries is discussed, and comparisons also are made with data on the more complex case of multiple-jet, reacting flows. A review is given of Langley investigations of parallel injection flow fields. Among these are single-jet studies of nonreacting, turbulent mixing (H2 in air and H2 in N2), and of reacting turbulent mixing (H2 in air) with both single and multiple jets. Implications of the results of the studies for scramjet fuel injector design are discussed.

R. Monti In AGARD Anal. and Numerical Methods for Invest. of Flow Fields with Chem. Resolions, Especially Related to Combust: May 1975 21 p. refs (For availability see N75-30359 21-311

Hybrid propellant combustion models (solid fuel and liquid oxidizer) are reviewed. The general equations for turbulent boundary layer combustion, together with the interface boundary conditions, are written Combustion theories and working formula for solid fuel regression rates assume different orders of magnitude for the characteristic time ratios of the relevant processes (i.e. fuel vaporization, gas-phase chemical reactions, and oxidizer diffusion) It is shown that the models based on linite characteristic time for diffusion and chemical reaction explain the experimentally observed regression rate dependence on both mass flux and combustion pressure.

SOME PROBLEMS AND ASPECTS IN COMBUSTOR MODELLING

F Suttrop In AGARD Anal and Numerical Methods for Invest of Flow Fields with Chem. Reactions, Especially Related to Combust May 1975 6 p (For availability see N75-30368

Development of a theoretical combustor model that predicts CO and NO emissions and is applicable to industrial burners as well as gas turbines is described Factors considered include: determination of the amount of NO formed in the flame front; selection of the correct rate constant for the reaction which controls NO formation; the temperature drop caused by radiation; and the effect of the initial amount of radicals on the NO

N75-30374 Sheffield Univ (England) Dept of Chemical Engineering and Fuel Technology.

MEASUREMENT IN TURBLEINT FLOWS WITH CHEMICAL REACTION

N. A. Chigier In AGARD Anal and Numerical Methods for Invest, of Flow Fields with Chem. Reactions, Especially Related to Combust. May 1975-18 p. rats (For availability see N75-30359 21-31)

Measurements in turbulant flows are considered particularly for their relevance to the prediction of flows with combustion. The relative accuracy of instruments used for the measurement of velocity, temperature, gas, and solid concentrations is discussed and examples are given of changes in the magnitudes of flame properties as measuring techniques have improved. The requirement of varying the time period for everaging according to the local conditions is stressed and it is shown that, under certain conditions, the averaging procedure can conceal the physical nature of the phenomena that is being measured. The disturbance to the flow and the errors introduced by using water-cooled pitot tubes for velocity, suction pyrometers for temperature, and relatively large water-gooled auction probes for particle and gas annivals are discussed. It is argued that future measurements in flames should be made with leser probes and that all measurements should be made optically, without the introduction of physical probes. Developments in laser anemometry and laser Raman spectroscopy are reviewed. Examples are given of measurement by laser probes of velocity in frames with swirl and of temperature and specie concentration in turbulent diffusion flames. The important role of accurate measurement in the formulation and testing of analytical and numerical prediction theories is stressed

SOME MEASUREMENTS AND NUMERICAL CALCULA-TIONS ON TURBULENT DIFFUSION FLAMES 634 n24 Th. T. A. Paauw In AGARD Anal. and Numerical Methods for invest, of Flow Field with Chem. Reactions, Especially Related to Combust. May 1875 11 p refs (For availability see N75-30359

Measurements and the result of calculations are presented for the combustion flow field in a conical furnace, constructed so that boundary layer approximations are valid. Two types of flames are observed, an attached and a lifted flame. Measurements of temperature, velocity, and the mass fractions of N2, O2. CH4, and NO are obtained for the radial profiles at different distances along the cone it is shown that the measured concentration of NO is sensitive to the flame type.

PROPERTIES OF ELECTROMAGNETIC HADIATION

J. Win. McGowan In AGARD Leser Hazards and Safety in the Mil. Environ. Aug. 1975 9 p refs (For availability see N76-11306 02-31)

The basic principles dealing with electromagnetic radiation were discussed, particularly as they relate to the development of the Laser and insofar as life processes are affected by light. It was pointed out that, although the electromagnetic spectrum extends over more than thirty orders of magnitude, that portion of it now dominated by the Laser only includes four. It is through this range that all life processes are affected by light and, in particular, the eye can easily be damaged by it.

N78-11308 Western Ontario Univ., London. Dept. of Physics. LASERS

J. Wm. McGowan In AGARD Laser Hazards and Safety in the Mil. Environ. Aug. 1976 12 p. refs (For availability see N76-11306 02-31)

Principles and properties of the laser were discussed in some detail together with a description of the various types of lasers and their applications

N76-11309 Army Environmental Hygiene Agency, Aberdeen Proving Ground, Md. Laser Microwave Div. INSTRUMENTATION AND MEASUREMENT OF LABER RADIATION

David H. Sliney In AGARD Laser Hazards and Safety in the Mil. Environ. Aug. 1975 9 p refs (For availability see N76-11306

New laser instruments and measurement techniques evolved during the past decade were reviewed. The measurements of primary interest in the evaluation of laser hazards are: output energy or power, pulse duration, beam profile and divergence, and pulse repetition frequency (PRF). The most useful types of detectors and hearn profile methods were discussed. Short-out check tests were also given.

N76-11310 Letterman Army Inst. of Research, San Francisco, Non-lonizing Radiation Div.

OCULAR EFFECTS OF LASER RADIATION: CORNEA AND ANTERIOR CHAMBER

Edwin S. Beatrice and Bruce E. Stuck In AGARD Laser Hazards and Safety in the Mil. Environ. Aug. 1975 5 p. rafe (For availability see N76-11306 02-31)

The effects of infrared laser radiation on the corner and skin of humans were considered. Three areas were discussed: normal anatomy and physiology of both tissues, summary of those laser systems which may interact with these tissues, and effects of these systems on tissues. It is pointed out that threshold damage to the eye from CO2 laser radiation is confined to the more superficial areas of the comes. At above threshold levels, damage is observed to the entire thickness, and some changes in the anterior chamber are observed.

N76-11311 Letterman Army Inst. of Research, San Francisco. Calif. Non-todizing Radiation Div.

OCULAR EFFECTS OF RADIATION: RETINA

Edwin S. Beatrice In AGARD Laser Hazards and Safety in the Mil. Environ. Aug. 1976 4 p refs (For availability see N76-11306

A discussion of threshold levels associated with injuries to the primate ratina from exposure to visible and near infrared laser radiation was given. It is explained that, while the ratins is subdivided into ten identifiable layers, the absorption site of the visible and near infrared laser sources is limited to the melanin granules of the retinal pigment epithelium. The mechanism of injury at the above threshold exposed site is thermal. The endpoint for the determination of threshold levels can be subdivided into three areas: grossly observable retinal opacity level, light microscopic cellular alteration at the distal photoreceptor and pigment epithelial level, and subcellular change at the magnification power of the electron microscopia level.

N76-11312 Royal Air Force Inst. of Aviation Medicine. Farnborough (England). DETERMINATION OF SAFE EXPOSURE LEVELS: ENERGY

CORRELATES OF OCULAR DAMAGE
R. G. Borland In AGARD Laser Hazards and Safety in the

Mil. Environ. Aug. 1975 6 p. refs (For availability see N76-11306 02-31)

Three techniques were used to define practical but safe criteria for use with laser systems. These are: inspection of the eye by optical means (ophthalmoscopy), fluorescein angiography, and microscopy (light and electron). The detection of damage is a form of quantal response and the determination of the threshold level is normally based on the energy or power which will result in a given probability of damage being detected. The energy correlates of damage depend on wavelength, pulse width or exposure time, repetition rate, tissue type and pigmentation, and ocular quality. This complex relationship necessarily limits experimental research to laser systems of special interest and so the interpolation of data to formulate overall sale exposure levels is necessary.

N76-11313 Army Environmental Hygiene Agenty, Aberdeen Proving Ground, Md. Laser-Microwave Div. DERIVATION OF SAFETY CODES. 1: USA EXPERIENCE David H. Sliney In AGARD Laser Hazards and Safety in the Mil. Environ. Aug. 1975 13 p refs (For availability see N76-11306 02-31)

A review of the problems encountered in setting safety standards and the complementary laser system classification and field safety controls since 1965 was presented. Originally, only two or three limits were provided. However, since 1972, a sliding scale of limits varying with exposure duration, wavelength, and PRF have been in use, are now standardized throughout the USA, and are described in the paper.

N76-11314 Royal Air Force Inst. of Aviation Medicine. Farnborough (England).

DERIVATION OF SAFETY CODES. 2: UK EXPERIENCE R. G. Borland In AGARD Laser Hazards and Safety in the Mil. Environ. Aug. 1975 6 p. refs (For availability see N76-11306

A review of laser safety codes in use in the United Kingdom since 1965 was presented. The initial codes were based on limited experimental data and so tended to be over-cautious. More recent studies have been related to the practical situation of ocular irradiation by parallel beams and have suggested that the retinal radiant exposure for damage increases with decreasing image size; it followed that a considerable relaxation of the recommendations published in 1972 was possible. The British Standards institute (BSI) has since then recommended adoption of the American Conference of Governmental Industrial Hygianists (ACGIH) exposure levels.

N76-11316 Royal Air Force Inst. of Aviation Medicine. Farnborough (England).

OFTHALMOLOGICAL EXAMINATION OF LASER WORKERS AHD INVESTIGATION OF LASER ACCIDENTS

D. H. Brennan In AGARD Lesser Hezards and Safety in the

Mil. Environ. Aug. 1975 11 p. ref (For evallability see N76-11306

Those espects of ocular structure and function which are relevant to laser induced damage in man were discussed, including the transmission and absorption characteristics of ocular tissues and the natural protective mechanisms of the eye. A acheme for the ocular surveillance of laser workers was presented with an evaluation of the role of the field and other specialized examinations. The procedure to be followed in the event of a laser accident was discussed. It is recommended that this involves a biophysical assessment of the accident with particular reference to energy or power densities which may have been incident on the cornea, as well as a detailed ocular examination. This may include fluorescein angiography, which has been found to be a more sensitive technique for detection of damage than ophthal-inoscopy in monkeys.

N76-11316 Army Environmental Hygiene Agency, Aberdeen Proving Ground, Md. Laser Microwave Div. LASER PROTECTIVE DEVICES

David H. Sliney In AGARD Laser Hezards and Safety in the Mil. Environ. 1975—11 p. refs (For availability see N78-11306 02-31)

The ideal characteristics of leser eye protective devices were presented and the present filter materials and goggle designs were compared with the ideal. Although the skin requires protection from lesers emitting in the ultraviolet and far-infrared regions at comparable exposure levels that may cause eye injuries, protection of the eye remains paramount.

Avail NTIS HC A14/MF A01

The development and use of laser anomometry in various French and German high-speed wind tunnels is discussed. In these studies the fringe type anemonister was used exclusively because it is insensitive to vibrations and high sound levels Moreover, this type of anemometer is supposed to give the most accurate results with respect to mean flow velocity and turbulence intensity. This is especially triu if electronic counters are used as data acquisition systems. Both the optical arrangements and electronic designs are described in detail. All the investigations described rated on the natural dust particles present in the flow as velocity indicators. As a result of binational cooperation it is shown that in the wind tonnels considered the size distribution of dust particles fulfils almost completely the requirements of negligible particles lay. With some applications in high speed tunnel testing it is proved that fasor anamometry is a standard measuring procedure and that it yields results which may not be obtained by other methods

Avail NTIS HC A14/MF A01

Measurements with a Laser Doppler Volocimeter (LDV) using the differential Doppler or fringe type of optical system were made in a variety of subsonic and supersonic flows. The application of this instrument at the Naval Surface Weapons Center (NSWC) to determine series of such distributions, to measure turbulence properties in supersonic boundary layers, to measure the mixing characteristics of two supersonic flows, and to measure the three-dimensional flow field around an axially symmetric body at large angles of attack in subsonic flow is discussed. Results show that the LDV can be a very useful tool for making nonintrusive measurements. Results also show that since the LDV measurements require micron-size particles to be present in the flow, care must be taken to insure that the particles will follow the flow accurately.

LASER VELOCIMETRY APPLIED TO TRANSONIC AND SUPERSONIC AERODYNAMICS

D. A Johnson W. D. Bachalo, and D. Moddaress. In AGARD Appl of Non-Intrusive Instr. in Fluid Flow Res. May 1976 12 p. refs (For primary document see N77-11221 02-31) Avail NTIS HC A14/MF A01

As a further demonstration of the capabilities of laser velocity in compressible aerodynamics, measurements obtained in a Mach 2.9 separated turbulent boundary layer and in the transonic flow past a two-dimensional airfoil section are presented and compared to data realized by conventional techniques, in the separated-flow study, the comparisons were made against pitot-static pressure data. Agreement in mean velocities was rushized where the pressure measurements could be considered raliable, however in regions of instantaneous reverse velocities. the laser results were found to be consistent with the physics of the flow whereas the pressure data were not. The laser data obtained in regions of extremely high turbulence suggest that velocity biasing does not occur if the particle occurrence rate is low relative to the turbulent fluctuation rate. Streamwise turbulance intensities are also presented. In the transonic airfoll study, velocity measurements oblained immediately outside the upper auriace boundary layer of a 6-inch chord MACA 54AO10 uirfoil are compared to edge velocities inferred from surface pressure measurements. For free-stream Mach numbers of 0.6 and 0.8, the agreement in results was very good. Dual scatter optical arrangements in conjunction with a single particle, nounter-type signal processor were employed in these investigations. Half-midron-diameter polystyrene upheres and naturally outurring condensed oil vapor sided as light scatterers in the two respective flows. Bragg-cell frequency shifting was utilized in the separated flow study

Avail NTIS HC A14/MF A01

Data reduction techniques are described to circumvent the problems of random, biased sampling of single scattering particle laser Doppler velocity measurements in turbulent flow. Two different methods are developed. For high mean data rates all statistical quantities are computed in an unbiased fashion through the use of time integrals. For low mean data rates statistical quantities can be computed in terms of ensemble averages where each event is weighed by the probability of its occurrence. The laster method will usually require a simultaneous measurement of at least two of the three velocity components of a single particle, and possibly all three depending on the shape of the local volume. These techniques allow reliable measurements to be extracted from the data in cases where the souttening particle number density is uncorrelated with the local velocity vector Other topics discussed include (8) minimum sampling rate required if time integrals are used to compute averages and if no spectral information is desired (b) frequency response of single scattering particle laser Doppler velocity, (c) apparent turbulence due to finite extent of measurement volume and curvature of velocity space correlation at the origin, and (d) flows for which leser Doppler velocimetry may not be a settefactory measurement method.

DEVELOPMENT OF PHOTON CORRELATION ANEMOM-ETRY FOR APPLICATION TO SUPERSONIC FLOWS

. B Abbiss In AGARD Appl. of Non-Intrusive Instr. in Fluid Flow Res May 1976 11 p rofs (For primary document see N77-11221 02-31) Avail NTIS HC A14/MF A01

The development is described of a laser enemometer based on a photon correlator for experimental applications in transonic and supersonic wind tunnuls at the Royal Aircraft Establishment. The equipment was designed to operate with a differential Doppler optical system in the backsoutter mode in order to minimize the problems associated with traversing and alignment. The light source is an argon-ion laser which can be operated simultaneously at several frequencies in the visible spectrum. After initial experiments with an unseaded laminar flow in a small test section at Mach numbers up to 2.5, two component measurements were made on the flow around a cone at vero incidence in a laminar supersonic strategim. For these experiments the strong lines at 488 and 5145 nanometers in the laser output were used. together with two Doppler difference optical systems and separate detectors. Controlled seeding with micron-sized particles was provided by an oil mist generator. The results of those experiments, together with those obtained with the same arrangement in a turbulent supersonic boundary layer, are presented. The principles of the photon correlation method are discussed and consideration is given to the experimental criteria which should be met in order to facilitate interpretation of the autocorrelation function.

MEASUREMENT OF PERIODIC FLOWS USING LASER DOPPLER CORRELATION TECHNIQUES

H. Barnes, Q. I. Daudpota, T. S. Durrani (Southhampton Univ. Engl.), I Grant (Napier Coll of Tech., Edinburgh, Scotland), and C. A. Granted. In AGARD. Appl. of Non-Intrusive Instr. in Fluid. Flow Res. May 1976 10 p refs (For primary document see N77-11221 02-31) Avail NTIS HC A14/MF A01

The application of photon correlation methods to the measurement of sinuspidally fluctuating flows is described it is shown that with a laser Doppler optical configuration the correlation function for the Doppler signal is periodic with zero order Bessel function damping and that the amplitude of the velocity porturbation can easily be determined by locating the position of zeros of the Bessel function. For a two beam configuration, the cross correlation function is a distorted form of the velocity probability density function. Experiments were performed in a low turbulence wind tunnel in the wake of a circular cylinder using photon counting techniques for the Doppler signal analysis. The results of these experiments show the characteristic forms taken on by the correlation functions in the different locations. Measurements of velocity perturbation amplitudes obtained by visual inspection of the correlegiams agree well with hot wire results. A curve fitting procedure for more accurate evaluation of the flow parameters is described

AVAIL NTIS HC A14/MF A01

Coherent Raman scattering offers new possibilities for measuring concentrations and temperatures in gas flows. This technique was achieved by means of an original apparatus using two CW lasers as excitation sources. This allows the measurement of local density fluctuations in a flow. The experimental arrangement is described, its performances are analyzed (temporal and spatial resolution), limitations of the method are studied (the leser emission is disturbed when the flow is inside the cavity), and further improvements are proposed. The first results obtained with a N sub 2 flow ere presented.

Avail NTIS HCA14/MFA01

Several factors concerning the use of the electron beam fluorescence technique to make time resolved density and temperature measurements in relatively high density turbulent flows are discussed. Experience derived from a recent study of 16.3 adiabatic tunnel wall boundary layer in helium is used to outline many difficulties to be encountered in the application of this broad bandwidth, nonintrusive technique to study hypersonic turbulent flows in general. Collision quenching, attenuation and other beam broadening effects are described. In addition, data analysis procedures often saymmetrically distributed about the mean fluctuations are discussed. For example, evidence is presented to show that most intensity data does not provide mean flow property information in general. Primary emphasis is on results obtained in halium with recent work by others in air and nitrogen flows cited, especially where differences exist.

The sounding of simple or coaxial, cold or hot free jets by optical systems makes up a measuring means external to the medium investigated. More especially, the use of radiometers measuring infrared emissions gives access to spatio-temporal data that are tightly coupled to turbulence parameters. These data can be obtained by crossed beam techniques. The physical meaning of the signals issued from the radiometers, as well as their interpretation after processing, are discussed and compared with those obtained by other types diagnostic, in spite of the difficulties pertaining to the optical system and to the crossed beam measuring technique, it is shown, as a conclusion, that this methodology does, in some precise cases, reach its objective: to characterize noise sources.

Avail: NYIS HC A14/MF A01

A modified technique in which the standing electromagnetic field induces a time verying fluorescent emission from liquid droplets doped with a suitable organic dye is described. The fluorescence consists of a band of wavelengths not including the incident inner light and therefore can be passed by a filter which blocks the laser wavelength. This can significantly improve the signal to come ratio or allow signal detection only from those particles in high rately added to the flow. An extensive study was carried out to determine factors which influence the quality of the fluorescence signal. The effect of dye concentration in the solvent and other environmental factors were investigated. Data obtained to date indicate that the fluorescence signal is of the same order of magnitude us the scattered light signal only In the case of a backscatter system.

THE TIME-OF-FLIGHT LASER ANEMOMETER

i. Lading In AGARD Appl. of Non-Intrusive Instr. in Fluid Flow Res. May 1976 20 p. refs (For primary document see N77-11221 02-31)

Avail: NTIS HC A14/MF A01

The time of flight laser anemometer is based on measuring the time of flight between two small volumes in space by correlation techniques. It is shown that this anemometer can generally give the same kind of information as can be obtained with a laser Doppler enamometer, and that in some specific cases the space time resolution is even better than for the loser Doppler anemometer. The uncertainties on the measured values are discussed in relation to the statistical properties of the mensuring system and signal processing. The effects of spatial and temporal velocity fluctuations are analyzed. With the anemorrieter it is possible to obtain a particle size versus particle velocity spectrum, provided that the particles are larger than the focal beam dismeters in the flow direction. The anemometer was used for measurements in a two phase flow surrounding a simulated fuel rod. The configuration was also used under extremely low light level conditions (an average number of photon counts less than one per transit through one spot) to measure gas velocity. Author

F. Cignoll, A. Coghe, U. Ghezzi, and S. Pasini. In AGARD. Appl. of Non-Intrusive Instr. in Fluid Flow Res. May 1 refs (For primary document see N77-11221 02-31) Avail. NTIS HC A14/MF A01 May 1976 11 p

The flow field in the wake of a blunt body was investigated by laser Doppler andmometry. The cold flow and the flow with chemical reactions was considered in order to determine directly the combustion influence on the flow field. Premixed methane-air

flame was obtained with a 20 mm inner diameter tube burner. A disc of the same external diameter was positioned, coaxially 30 mm higher on the burner mouth. Both the situations, where the blunt body is only an obstacle generating a wake and where it acts as a flame stabilizer, were analyzed. Flame front crossing, in laminar premixed flames, was also carefully analyzed Experiments were carried out by means of different LDA signal processors and in different conditions of scattering particles. Both the mean and fluctuating valocities were measured in the exist and radial directions. The analysis of results was not intended to a flame structure discussion, but rather to a critical exemination of LDA measurements in connection with some specific problems: particle behavior, turbulence effects, resolution of turbulence fluctuations, minimum particle concentration, performances of different LDA signal processor

Avail. NTIS HC A14/MF A01

The development of a three component laser Doppler velocimeter is described. It utilizes four incoming beams which are all frequency shifted. Three of the beam propagate in one plane and form three dual beam arrangements. Two of these are used to measure two independent velocity components in this plane. The fourth beam propagates outside this plane and forms together with one of the first three beams a third dual beam arrangement, which measures a velocity component in a direction out of the plane formed by the first three beams. The frequency shifts are chosen so that three signals can be identified corresponding to three independent directions. The system is to be tended to measurements in five points simultaneously. The signal is led into three phase looked loops and the frequencies generated by their local oscillators are counted. sumpled digitally and stored on magnetic tape for later processing on a digital computer.

lonospheric heating by powerful radio waves holds promise for establishing new techniques in the aeronomy of D, E and F-regions. This survey reviews the observed phenomena associated with absorption of HF waves in the context of present theoretical understanding of plasma temperature and density changes, enhanced visible airglow emission and parametric excitation of plasma waves. Cooling rates and electron thermal conductivity are attainable from optical and incoherent scatter, measurements of the spatial and temporal changes in electron temperature. Cross modulation experiments or partial reflection techniques could be used to simultaneously measure there changes from which the ambient effective recombination rate and its electron temperature dependence could be inferred. The decay of enhanced sirglow yields an estimate of the quenching coefficient and hence the neutral density provided the interaction is a local one. The decay of enhanced plasma waves measures the electron-ion collision frequency at night and the photoelectron flux during the day. Superthermal plasma wave intensities also act as a tracer of density irregularities and plasma drift since parametric pumping ants over a very narrow range of sittludes

PARAMETRIG INSTABILITIES IN THE IONOSPHENS EXCITED BY POWERFUL RADIO WAVES OBSERVED OVER ARECIBO

W. E. Gordon and H. C. Carlson (Arecibo Obs.) /n AGARD Notilinear Effects in Electromagnetic Wave Propagation May 1974 17 p. refs (For availability see N74-31812 21-13) Enhancements of various features of the incoherent scatter

spectrum are observed when the ionosphere is illuminated with powerful, high frequency radio waves. The radio waves excite plasma instabilities producing lines or more complex spectral features near the local plasma frequency, at the local ion-acoustic frequency, near the local gyrofrequency and twice the gyrofrequency. The enhancements occur in a thin slab as observed by the incoherent scatter radar and at both upshifted and downsnifted frequencies with respect to the probing radar frequency. The enhancements are observed to vary with time when the high frequency transmitter that produces the radio wave excitation is held at constant power, and to very with time as the high frequency transmitter is turned on or off.

T. Hagfors and C. J. Zamlutti. In AGARD. Nonlinear Effects in Electromagnetic Wave. Propagation. May 1974. 13 p. refs Sponsored in part by NASA (For availability see N74-31612.

The Aronibo 430 MHz incoherent scatter rader (ISR) was used to monitor the effects of modifying the ionosphere by a high power HF transmitter feeding the 305 m reflector entennia When in the ordinary magnetoionic mode parametric instabilities develop in the ignosphere near the reflection level. Manifestations of these instabilities are the strong enhancement of Langmuir psolliations in the direction of the ISR beam at a wavelength of 35 cm and the simultaneous much weaker enhancement of ion oscillations in that direction. The spectral analysis of the enhanced peak with a height resolution of 2.4 km shows that the ionic mode enhancement most often has a double humped frequency spectrum corresponding to up- and down-going ion acoustic waves. The shape of the frequency spectrum is interpreted in forms of a stable oscillation which is driven by a accordary electrostatic field osused by nonlinear interaction of Langmuir views within a cone centered on the magnetic field and by the scattering of the pump field on stable Langmuir waves travelling niong the direction of the ISR.

George Schmidt In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 5 p refs Sponsored in part by AEC (For availability see N74-31812 21-13)

Parametric instabilities produced by electromagnetic waves propagating in a magnetic field free plasma are reviewed. The discussion is based on the use of the pondersmative force as the basic physical mechanism responsible for these instabilities. If the plasma is bounded the threshold power is non-zero even in the absence of damping, and may be the dominant factor in determining threshold and growth rate values. The threshold for stimulated Raman scattering increases in the presence of plasma density gradients, while temperature gradients have a similar effect on simulated Brillouin scattering. The finite cross section of the pump wave determines the undamped threshold for the filamentation instability. In a nonuniform plasma stimulated Ramen backscattering becomes very strong in the neighborhood of the point where the pump frequency is twice the local plasma Author

R. L. Stenzel, A. Y. Wong, O. Amush, B. D. Fried, and C. F. Kennel. In AGARD. Nonlinear Effects in Electromagnetic Wave Propagation May 1974 18 p rafs (For availability see N74-31812

(Contract F30602-72-C-0304)

A large quiescent steady state plasma device has been constructed for experiments on parametric mode coupling instabilities produced by an S-band electromagnetic pump matched to the local plasma frequency in a weak, controllable plasma density gradient. One purpose of this experiment is to study the linear instabilities, and their nonlinear saturation, produced by HF excitation irradiation of the F-region. In that vicinity linear conversion from the incident electromagnetic waves (EMW) to electrostatic waves (ESW) at pump frequency is observed. When the pump intensity exceeds a certain threshold lower frequency ESW and ion acoustic waves are parametrically generated which are polarized along the density gradient and which, within measurement accuracy, satisfy frequency and wave vector matching conditions. Amplification by the pump of launched ion accustic waves along with the simultaneous appearance of a parametrically matched ESW has been observed. Inserting two pump frequencies, separated by the ion acoustic frequency, has been observed to ureate double resonance excitation. relevance of those to conospheric observations are discussed.

MODIFIED ELECTRON DISTRIBUTION FUNCTION DURING PARAMETRIC INSTABILITIES

Jerome Weinstock and Bandel Bezzarides In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 6 p refs (For availability see N74-31812 21-13)

A calculation is made of the heating of electrons by parametrically expited Langmuir wave turbulence in a homogeneous plasma. The number of hot electrons is determined by a kinetic equation in which the effects of turbulence are described by a stochastic wave diffusion tensor. Both resonant and resonant broadened wave-particle interactions, as well as the angular distribution of Langmuir waves, are important. The kinetic equation is solved for a steady state by balancing the surbulent diffusion with a relaxation collision term. It is predicted that suprathermal electrons exist to velocities as large as the fastest growing phase velocity.

Recent calculations on the nonlinear saturation spectrum of the parametric decay instability are described. The initial calculations did not use the correct expression for the spontaneous emission term and were aimed at obtaining the distribution of spectral energy in the unstable part of wave vector space. Results of those initial calculations are combined here with the correct expression for the sponteneous emission term to obtain the distribution of spectral energy in the stable part of wave vector space. These latter calculations are believed to be relevant to the interpretation of the so called plasma line spectra obtained in lonospheric heating experiments at Arecibo. Puerto Rico.

D. Arnush (Hiroshima Univ.), K. Nishikawa, B. D. Fried, C. F. Kennel, and A. Y. Wong In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 7 p refs (For availability see N74-31812 21-13) (Contracts AT(04-3)-34: F44620-73-C-0007)

Reviewed is a general theory of the parametric instabilities in a plasma driven by a long wavelength electric field with two pump frequencies which lie near the resonant frequency for Langmuir oscillations. A general dispersion relation in terms of linear susceptibilities, is derived by retaining, on a selective basis, terms of fourth order in the pump amplitudes. Illustrative calculations, appropriate to the longsphere, are carried out using resonent approximations. A lowering of the net power threshold for instability is found in both cases for E-layer parameters, i.e., when the linear damping rate of the electronic wave is large compared to omega. In addition, in both the E- and F-layers, a coupling between the decay and oscillating two stream instabilities occurs when delta is approximately equal to omega. It is suggested that since the oscillating two stream is an absolute instability which is ordinarily not generated because of its high threshold, double resonance stimulation of this mode may enhance saturated wave amplitudes.

Threshold and growth rate for atimulated Brillouin scattering are calculated for a uniform magnetoplasms. These are then compared with the threshold and growth rate of a new thermal inatability in which the nonlinear Lorentz force felt by the electrons at the best frequency of the two electromagnetic waves is replaced by a prossure force due to differential heating in the interference pattern of the pump wave and the generated electromagnetic wave. This thermal instability, which is still essentially stimulated Brillouin scattering, has a threshold which is especially low when the propagation vector of the beat wave is almost normal to the magnetic field. The threshold is then considerably lower than the threshold for normal stimulated Brillouin scattering and therefore this new instability is probably responsible for the generation of large scale field aligned irregularities and ionospheric N74-31828 Bell Telephone Labe., Inc., Murray Hill, N.J. NONLINEAR THEORY OF INSTABILITIES IN THE EQUA-TORIAL ELECTROJET

Andre Rogister In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 13 p rafs (For availability see N74-31812 21-13)

it is suggested that the stabilization of Type I irregularities has two aspects: In a first step the turbulence inhibits the formation of large currents and maintains the plasma in a state relatively close to marginal stability; In a second step, energy is transfered by two-dimensional nonlinear wave coupling processes from the linearly growing modes propagating mainly in the direction of the electron drift velocity to linearly damped ones propagating in other directions. This transfer process open the aperture of the cone containing the directions of propagation of suprathermal waves. It is also suggested that stabilization of Type II irregularities mainly occurs via one-dimensional wave-wave scattering processes which transfer the energy from large wave-lengths. where it is generated, to small wavelengths, where it is absorbed by diffusion; the process extends toward larger wavenumbers the spectrum of suprathermal waves. Most of the observed features of Type I and Type II irregularities can be explained by these

PLASMA MECHANISMS FOR PULSAR EMISSION

J. W. Buckee, S. Grounds, L. C. M. Miranda, and D. TerHaar In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 8 p refs (For availability see N74-31812 21-13)

A partial analysis is presented of the nonlinear processes occurring in a strongly magnetized plasma through which a beam of relativistic particles is passing. The conversion of longitudinal plasmons into transverse waves through Compton scattering is considered and it is found that the frequency of these waves lies close to the plasma frequency which lies in the radio band for the plasma. Radio waves beamed at right angles to the magnetic field are linearly polarized. These characteristics can be shown to be conserved in the propagation of the transverse waves through the magnetosphere and are in good agreement with observational pulsar data. The processes considered can produce the observed large radio brightness of pulsars. Author

A SELF CONSISTENT THEORY OF TRIGGERED VLF EMISSIONS

D. Nunn and M. J. Rycroft (Southampton Univ., England) In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 15 p refs (For availability see N74-31812 21-13)

The nonlinear interaction of evolution resonant electrons with VLF radio waves is used to explain the phonomenon of VLF emissions triggered by whiteler mode signals propagating in the earth's magnetosphere, it is found that in an inhomogeneous medium resonant particles become stably trapped in the wave and make a dominant contribution to the nonlinear resonant particle current. This current continuously modifies the wave field and effectively causes the emission. This simplifying feature makes possible a fully self-consistent simulation of the triggering process. The computer model described in this paper successfully produces rising and falling tones similar to those observed experimentally. Sideband stability and the origin of spectral structuring in banded chorus are also discussed.

N74-31830 Comissão de Étudos da Energia Nuclear, Lisbon (Portugal). Inst. Superior Techico. WHISTLER TRIGGERED EMISSIONS

A. L. Brince In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 11 p refs (For availability see N74-31812 21-13)

The electromagnetic radiation from energetic particles evolving in the geomegnetic mirror is used to describe the main phase of emissions artificially stimulated by signals propagating in the whistler mode. Those particles are in a cyclotron resonance with the triggering whiatier of arbitrary obliquity in the vicinity of the equator (onset region); their velocity distribution becomes unstable to the whistler mode through the nonlinear evolution of the wave-particle interaction. The obtained spectral shapes reproduce most of the forms observed in triggered emissions of short duration.

fasayoshi Tajiri In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 11 p refs (For availability see N74-31812 21-13)

Nonlinear modulation of the electromagnetic waves propagating paralled to a magnetic field is investigated by means of a modification of the reductive perturbation method developed by Taniuti and Yajima. The Vissov equation is reduced to a modified nonlinear Schrödinger equation which includes additional nonlinear terms. It is conjectured that these terms arise from the week but continuous resonant action that takes place between the wave and particle velocity.

INTRODUCTORY SURVEY: NONLINEAR EFFECTS IN PLASMA RESONANCES AND ION SHEATH

Kristen Folkstad In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 8 p refs (For availability see

N74-31812 21-13)

Some nonlinear properties observed in ionospheric topside soundings are considered and particle generated emissions in the near space environment are discussed. The energy transfer which takes place between interacting waves in a plasma is determined by their phase relationship. Criteria for distinguishing between the cases of strong and weak coupling in three wave interactions are described. A useful quantum mechanical analogy pertaining to weakly interacting random waves is mentioned. The possible role of the ion sheath as a source for nonlinear signal generation is evaluated. Author

NARROWBAND RADIO NOISE IN THE TOPSIDE IONO-

H. G. James, E. L. Hagg, and D. L. P. Strange. In AGARD Nonlinear Effects in Electromagnetic Wave Propagation 1974 18 p. refs (For availability see N74-31812 21-13)

Strong narrow bands of radio noise at frequencies near 2 and 4 MHz are occasionally observed by the ISIS satellites at auroral latitudes. A characteristic smooth peak in amplitude is often observed at the upper frequency limit of the lower frequency noise band. A self consistent interpretation for this part of the spectrum is proposed involving waves propagating upward from below the spacecraft. Ray tracing has been applied to the spatial geometry of the noise region to find the point source height for that part of the spectrum exhibiting the smooth peak. This source is located at altitude where the upper hybrid frequency, f sub T equals twice the electron gyrofrequency, 2 f sub H. Furthermore the observed peak frequency, f, satisfies the relation f = f sub T = 2f sub H. The condition f sub T = 2f sub H is important because, according to the hot-plasma wave dispersion theoryit defines an ionospheric height above which electrostatic-to-electromagnetic-o-mode wave conversion is more probable than below it. There is some evidence that the noise band near 4 MHz originates from the same source is the smooth peak compo-

RESONANCE PHENOMENA OBSERVED ON MOTHER-DAUGHTER ROCKET FLIGHTS IN THE AURORAL IONO-

K. Folkestad and J. Troim In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 15 p refs (For

availability see N74-31812 21-13)

Swept frequency transmissions in the HF band on mother/ daughter rocket flights have revealed certain resonance frequencies where the transmitted atimulus evidently excites nonlinear mechanisms somewhere along the propagation path. The nonlinear effects are disclosed by notable signals being detected in receivers whose pass bands differ from the frequencies of the generating signals. It appears that major experimental features may be explained in terms of the theory of resonance cones in an anisotropic propagation medium. For the plasma parameters of the lower longsphere such resonances may exist in the lower branch for frequencies below the electron gyrofrequency, and in the upper branch for frequencies between the plasma frequency and the upper hybrid frequency. Graphs of the admittance measured at the terminal of the transmitting antenna show a very pronounced dependence upon the level of the driving

MODIFICATION OF THE PLASMA IMPEDANCE OF AN ANTENNA DUE TO ION SHEATH INDUCED MONLINEARI-TIES

H. Thiemann, R. Kist, E. Neske, and K. Rebstock. In AGARD Nonlinear Effects in Electromagnetic Wave Propagation 1974 9 p refs (For availability see N74-31812 21-13)

Measurements with a cylindrical sensor in a laboratory plasma applying large RF voltages showed specific modification of the impedance around series resonance. The purpose of the work presented here is to understand this modification in terms of sheath induced nonlinearities. A nonlinear differential equation derived from a network representing the sheath-plasma-system has been solved numerically in a general way. A corresponding computer program determined the voltage drop across the ion sheath, the Fourier Spectrum of the RF current through the system and its resulting impedance. Numerical results show that scattering of RF energy into higher harmonics of the frequency applied is not important around series resonance. The measured impedance modification when varying the RF voltage can be understood using the concept of an effective sheath resistor. defined by integration of the differential resistor of the sheath's current-voltage characteristic over one period of the voltage drop across the sheath.

N74-31837 SIGMA Association, Hamburg (West Germany). RESONANCE FREQUENCY OF AN IONIZED LAYER IN DEPENDENCE ON LAYER THICKNESS

C. Fengler In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 5 p refs (For availability see N74-31812 21-13)

An ionized symmetric layer gets excited by an electromagnetic pulse. The evaluation of the pulse response violds a resonance frequency in dependence on layer thickness. The oscillation occurs above a minimum thickness of the layer only. At large layer thickness the frequency of oscillation asymptotically approaches the plasma frequency.

R. A. Smith and R. G. Looh (Warrnambool Inst. of Advanced Education, Victoria, Australia) In AGARD Nonlinear Effects in May 1974 14 p refs (For Electromagnetic Wave Propagation

availability see N74-31812 21-13)

Pulse wave interaction experiments using disturbing gyrawaves radiated by an aerial array of 40 dipoles are described. Steady state and transient changes in the amplitudes and phases of 1.78 and 2.12 MHz wanted pulses have been measured for transmitted powers at the gyro-frequency (1.615 MHz) in the range 0.7 - 500 kW. The wave interaction effects have been computed using a model of the behavior of slow electrons in air which links properties for the thermal energy known from ionospheric wave interaction experiments to properties for energies well above the thermal known from leboratory experiments. Excellent agreement with the experimentally measured amplitude and phase changes is obtained over the entire power range. The effects of night-to-night variability of the lower E region on the temperature rise and the factors which limit it, are dis-

DOUBLE CROSS MODULATION IN THE D-REGION

G. C. Rumi In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 15 p refs (For availability see N74-31812 21-13) (Grant NSF GP-5452)

An experiment of cross modulation in the lower D-region that made use of 2 relatively high frequencies is described. Its peculiarity was that the received wanted wave - on account of its relatively high frequency - contained a relatively strong extraordinary component together with the ordinary component. Such an echo was received alternatively by means of circularly and linearly polarized antennas, so that both amplitude cross modulation and cross modulation of the plane of polarization were detected. The discrimination between these two kinds of cross modulation was obtained just by shifting from one kind of antenna to the other. Since the experiment produced two pieces of information analytically related to the two knowns of the ionosphere at a specific height, namely the electron density, and its collision frequency, both of them were determined for heights ranging between 70 and 40 km.

N74-31842 Leicester Univ. (England). Dept. of Physics. MODIFICATION EFFECTS IN THE IONOSPHERIC D-RE-GION

Tudor B. Jones In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 6 p refs (For availability see N74-31812 21 13)

Nonlinear affects are observed during D region heating experiments using the high power transmitter at Platteville, Colorado. The first experiments, in which the power and frequency of the modifying transmitter were varied, indicate that the electron temperature changes are greater than perturbation magnitude. Experimental results are in good agreement with cooling due to the excitation of the rotational bands of molecular nitrogen. Later experiments, in which two frequencies are transmitted simultaneously, indicate that nonlinear frequency mixing may occur when the frequency difference is equal to the gyro-frequency. Author

NUMERICAL SOLUTION OF A PROBLEM OF NONLINEAR WAVE PROPAGATION THROUGH PLASMAS

L. M. DeSocio and G. Gaffuri In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 10 p refs (For availability see N74-31812 21-13)

The self-interaction of an electromagnetic wave propagating through a plasma layer has been considered as a typical example of nonlinear effect in the ionosphere. For the plasma, the indicative values of the physical characteristics of the D region have been considered. Quasi-longitudinal and non derivative propagation have been assumed and the electron heating is supposed to be described by Bailey's equation. The problem of determining the changes of the modulation index, the second harmonic distortion and the total absorption of both the ordinary and extraordinary waves has been solved numerically in an extensive range of values of the characteristic parameters.

THE IDNOSPHERIC PROPAGATION OF THE MODULATED WAVES WITH CARRIER FREQUENCIES FAR FROM AND VARYING AROUND THE GYROFREQUENCY

M. Cutolo, P. DiMalo, G. Gaffuri, G. Agnelli (Osservatorio Astronomico di Rome, Italy), F. Fabbri (Osservatorio Astronomico di Rome, Italy), M. Iannello (Osservatorio Astronomico di Rome, Italy), R. Flagg (Florida Univ.), and W. Greenman (Florida Univ.) In AGARD Nonlinear Effects in Electromagnetic Wave Propagation May 1974 13 p refs (For availability see N74-31812 21-13)

The self modulation phenomenon has been studied with oblique and with vertical incidence and with C.W. and pulse techniques. The C.W. experiments to demonstrated that the phenomenon clearly depends on the power emitted by the radio transmitting station. While the transmissions with C.W. were made with a carrier frequency far from the local gyrofrequency. the pulse transmissions were made with a carrier frequency varying around the gyrofrequency. The experiments have shown that it is possible to have demodulation or overmodulation and a resonance curve when the carrier frequency varies around the local gyrofrequency. The exportments made during the total solar sclipse of 7th Merch 1970 are also discussed.

N76-16257 Stanford Research Inst., Arlington, Va. DEFINITIONS AND FUNDAMENTALS OF ELECTROMAG-NETIC NOISE, INTERFERENCE, AND COMPATIBILITY

G H Hagn In AGARD Electromagnetic No. - Interference and Compatibility Nov 1975 24 p refs (For availability see

The terms electromagnetic noise, interference, and compatibility are defined, and some of the different definitions for these terms in current usage are discussed with emphasis on international definitions. For this paper, noise is defined as all electromagnetic energy except that associated with the dualred signal for a specific system of Interest. Interference is considered to be an undesirable effect of electromagnetic noise upon a system or subsystem rather than as a cause or source of noise. Electromagnetic compatibility is the condition that prevails when telecommunications equipment is collectively performing its individually assigned functions in a common electromagnetic environment without causing or suffering unacceptable interferonce. Selected aspects of the fundamentals of noise, interference, and compatibility are discussed.

ATMOSPHERIC DISCHARGES AND NOISE (AND COM-MUNICATIONS SYSTEMS INTERFERENCE REDUCTION) M. M. Newman and J. D. Robh In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 22 p refs (For availability see N76-16256 07-32)

Most studies of atmospherics in the past have dealt with the subject on the basis of the frequency domain as a linear phenomenon. From the special point of view of working to improve communications systems performance, there are advantages to be derived in viewing the problem in the time domain. Considered are broadband measurements, up to 200 megahers, of the fine structure of radiation from individual discharges, as well as longer consecutive records of the character and spacing of pulse components of branching streamers and repeated discharges. which have hitherto been unavailable. Direct lightning interception studies are discussed in relation to discharge noise characteristics. Research on artificial lightning discharge noise propagation and reception at various distances is presented as a unique tool for atmospherics propagation studies

N76-16269 Stanford Research Inst., Arlington, Va. MAN-MADE ELECTROMAGNETIC NOISE FROM UNINTENTIONAL RADIATORS: A SUMMARY
G. H. Hagn and R. A. Shepherd In AGARD Electromagnetic Noise interference and Compatibility Nov. 1975 24 p. refs

(For availability see N76-16256 07-32)

Considered is the noise from electrical and electromechanical devices that are not designed as intentional radiators but that produce electromagnetic energy as a by-product. The emphasis here is on description of the noise from electrical power transmission and distribution lines and from vehicle ignition systems; these two sources are known to be important below and above 20 MHz, respectively. Other sources are mentioned, and prediction of the composite environment due to unintentional radiators is considered.

Recent tests of signals observed through the ionosphere. the solar wind, and a laboratory plasma have revealed a surprising consistency in parameters describing the first order statistics of a signal caused to scintillate by a randomly structured plasma This paper describes a means for exploiting these new findings in a transionospheric communication channel model.

N76-16263 SIGMA Association, Hamburg (West Germany). THE INFLUENCE OF PARTICULAR WEATHER CONDITIONS ON RADIO INTERFERENCE

C. Fengler In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 10 p refs (For availability see N76-16256 07-32)

The various propagation properties of the atmosphere are associated to the variation of the refractive index. A stratified atmosphere shows due to the meteorological parameters a strong change which corresponds for example to variations of parameters as k-factor or radio horizon and noise temperature. The case of an atmosphere with embedded discontinuities is illustrated by experimental results, which were obtained on line-of-sight ground links, links with a distance near the radio horizon, transhorizon links as well as earth-space links it concludes that most radio interference is to be expected during days with strong radiation and the influence of cold fronts.

ELECTROSTATIC CHARGES AND THEIR PERTURBING EFFECTS ON RADIO COMMUNICATION [LES CHARGES ELECTROSTATIQUES ET LES PERTURBATIONS QU'ELLES ENTRAINENT DANS LES LIAISONS RADIOELECTHIQUES
Charles Fevrot In AGARD Electromagnetic Noise interference and Compatibility Nov. 1975 4 p in FRENCH (For availability see N76-16256 07-32)

The following areas related to the effect of electrostation charges on aircraft radio communication were discussed: (1) electrostatic charges and potential distribution on the surface of aircraft. (2) generation of these charges. (3) jamming effects, (4) suggested solutions. High electrostatic potential differences may exist between the metallic surface of siroraft and the surrounding air, or between two neighboring points of an insulating surface, although metallic surfaces may be assumed to be equipotential. Such charges may be generated by phenomena linked to the surrounding atmosphere, the aircraft itself, or other special situations (such as in flight refuelling, braking on a dry runway, etc.) Radio jamming resulting from these charges takes the form of a general increase in background noise and, in certain cases, may be aggrevated by noise resulting from sudden avalanche discharges. Suggested solutions include the development of improved paints with better conductivity properties.

ANTENNA RESPONSE TO RANDOM ELECTRIC FIELDS DUE TO THERMODYNAMIC DENSITY FLUCTUATIONS IN

R. Grabowski In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 11 p refs (For availability see N76-18258 07-32)

Thermodynamic density fluctuations of positively and negatively charged components in a plasma are responsible for the occurrence of random electric fields. The antenna response to these fields may be characterized by the quadratic or power spectrum of the voltage fluctuations in a measuring device connected with the antenna. The response is dependent upon the antenna configuration and is described as a filtering effect in wave vector space. Theoretical quadratic spectra are presented for equilibrium plasmas streaming parallel to the antenna axis. The bulk velocity has a strong influence upon the shape of the spectra, especially as it is the cause for a periodic fine struc-

N78-16268 Technische Hogeschool, Eindhoven (Netherlands). THE INFLUENCE OF FREQUENCY AND RECEIVER APERTURE ON THE SCINTILLATION NOISE POWER

M. J. M. VanWeert In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 10 p refs (For availability see N78-16256 07-32)

Some properties of the scintillation noise power are discussed. The used model is essential the same as used by Lee and Harp. Some calculations of different statistical properties of the scintillation noise are shown. Special attention is given to the influence of receiver sperture and frequency on admiliation noise power. It is shown that both parameters have a significant influence on amplitude scintillation, but hardly on phase scintillation. This behavior is explained. To decide whether scintiliation does have a significant influence on the performance of a communication link, the total scintillation noise power is compared with thermal noise power on an earth to satellite path. GENERAL EMC SPECIFICATION OR SYSTEMS ORIENTED EMC SPECIFICATIONS

D. Jaeger /n AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 12 p (For availability see N76-18258

To ensure electromagnetic compatibility in systems, EMC equipment specifications are required to limit for each unit the interferences emitted and specify a certain degree of unsusceptibility to interference signals. An examination is made as to whather it is more favorable to use a general EMC specification or system oriented specifications for this purpose. The following solution is obtained. The test methods and the test philosophy should be uniform for all systems. MiL-STD 462 (+ 463) could represent a good basis. However, updating and expansion in various respects seem desirable. As far as the limit values are concerned, it becomes evident that the characteristics of the systems themselves, their environment, and the system in conjunction with which they must possibly function differ too greatly. Establishing system related limit values is considered the optimum solution.

ELECTROMAGNETIC NOISE SPECIFICATIONS [SPECIFI-CATIONS EMC]

J. C. Delpech in AGARD Electromagnetic Noise interference and Compatibility Nov. 1975 21 p. In FRENCH (For availability see N76-18256 07-32)

Various EMC standards and specifications now in use were compared, with special emphasis on those applicable to alribone systems. The essential similarities and differences between these specifications were pointed out, in relation to the following type of tests used, frequency bands applicable, degree of required tolerance demanded, operating regime specified, and recommended hardware. The following points were also emphasized (1) the lack of adequate tests required by certain specifications (such as those used to evaluate the uninerability of numerical equipment), (2) the new tests required in the most recent specifications, (3) the tack of precision and unsatisfactory matching between certain limits which have been observed experimentally, and (4) the superiority of certain specifications in relation to the measurement principles and instruments used. Transl. by Y.J.A.

N76-16272 Stanford Research Inst., Arlington, Va. A STATUS REPORT OF THE IEEE/ECAC ELECTROMAGNETIC COMPATIBILITY FIGURE OF MERIT COMMITTEE G. H. Hagn and M. N. Lustgarten (IIT Res. Inst., Annapolis, Md.) /n AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 15 p. refs (For availability see N78-18256 07-32)

A practical technical procedure is devised for specifying an electromagnetic compatibility Figure of Merit (FOM) for various electronic devices and systems. An EMC FOM for single channel voice communication systems, based on the channel denial concept. was developed by using a building block approach. The building block approach involves the use of relatively simple scoring formulas for selected EMC parameters, which are then linearly combined, with appropriate weighting factors, to calculate equal to 10 db in a moderately dense co-site environment. The parameter acoring equations were developed to reflect the frequency spectrum denied by each parameter. The weighting factors for the building block approach were determined by running a computer program that kept track of the number of channels denied by each parameter. Example calquiations for HF, VHF. and UHF systems are given, and the interpretation of the scores is discussed.

N76-16273 Ministry of Defence, London (England). ELECTROMAGNETIC COMPATIBILITY IN MILITARY AIRCRAFT

D. H. Hight and W. A. Kelly. In AGARD. Electromagnetic Noise Interference and Compatibility. Nov. 1975. 5 p. ref (For availability see N76-16256.07-32).

Common sources of electromagnetic compatibility problems ar3 outlined and the difficulties confronting engineers who are responsible for producing successful aircraft weapon systems are discussed. A definition of EMC is given within the context of an aircraft weapon system. EMC problems can be minimized by: defining clearly the requirements of the weapon system; translating this requirement into an overall system specification; defining subsystem and installation specifications; writing an EMC control plan, and producing a detailed test plan.

N76-16274 Lucas Aerospace Ltd., Hemel Hempstead (England). ELECTROMAGNETIC COMPATIBILITY CONTROL PLANE P. D. Campbell In AGARD Electromagnetic Noise interference and Compatibility Nov. 1975 21 p. refs (For availability see N76-16256 07-32)

The spectrum and level of radio interference have been measured for years and unwanted omissions reduced retrospectively. This remedial approach is now recognized as inefficient but the concept of electromagnetic unripptibility as a
design parameter still requires emphasizing. The devices, circuits,
components and constructional details which can contribute to
the creation, conduction and emission of unwanted signals are
indicated and means whereby their effects can be minimized
are examined. The problems arising in creating and implementing
a control plan for the development of a typical piece of electrical
equipment are outlined and the difficulties experienced in balancing
operational, theoretical, practical and contractual requirements
are highlighted.

A CASE FOR AN EVALUATION AND ADVISORY SERVICE E.M. Frost In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 5 p (For availability see N76-16256 07-32)

The requirement to exchange, interwork and co-site equipments and systems, coupled with the widening use of semiconductor devices for new as well as traditional applications, has led to the concept of an overall Electromagnetic Compatibility (EMC) activity. However, there is no generally accepted definition for EMC as separate interests are tending to retain their own limited interpretations. It is believed that this is causing interface difficulties that will prevent EMC adapting itself sufficiently rapidly to deal with this changing and expanding electronic situation. After considering EMC as a typical poliution situation a suggestion is made for an evaluation and advisory service that would provide an interface between other EMC and allied activities and also act as a focus and creative development point for new ideas and techniques.

INTERFERENCES IN FREQUENCY MODULATION SYSTEMS
[INTERFERENCES DANS LES SYSTEMES A MODULATION
DE FREQUENCE NO. 21)

G. Crecombette in AGARD Electromagnatic Noise Interference and Compatibility Nov 1975 16 p in FRENCH, ENGLISH summary (For availability see N76-18255 07-32)

Interference problems applicable to telephone radio links with multiplexing reported in frequency (FDM-FM) were discussed A general treatment applicable to all FM links was first presented, including: (1) typical organization of links and equipments, (2) effects of disturbances on the operation of equipment (capture of AGC and limiters) and on overall performance inoise after demodulation), (4) procedures used to reduce the effects of disturbances, and (5) calculation of the level of disturbances from the radiation diagrams and application to two special cases. The rest of the report was limited to FDM-FM telephone radio links with moderate to large ospacities. Measurement results of reciprocal perturbations between different radio links of normal capacity were presented. Finally, radiation pattern diagrams used in the design of a network system were illustrated.

N76-16277 Army Electronics Command, Fort Monmouth, NJ RADAR INTERPERENCE REDUCTION TECHNIQUES William Fishbein, Reinhard Olesch, and Otto Rittenbach In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 23 p. refe (For availability see N76-16256 07-32)

Techniques are described, applicable to radar, which enhance the compatibility of multiple systems in limited frequency space By appropriate combination of multiple frequenties, the spectral occupancy of a signal can be reduced through pulse shaping. without sacrifice in range resolution. This method is extended to continuous wave radar, resulting in sidelohe reduction without amplitude modulation. A function is defined relating mutual interference of two systems in terms of their waveforms, physical and spectral proximity, and is used as a measure of interference. Ordinary single sideband techniques are modified and applied to rader to reduce spectral width. Considerations for interlacing the discrete line spectra of several radars are given. They include single sideband processing of unidirectional doppler signals and a step scanning scheme which permits increasing the allowable pulse rate. Author

APPLICATION OF PROGRAMMABLE CALCULATORS TO EMC ANALYSIS

J. P. Georgi (Dept. of Defense) and Paul D. Newhouse (ITT Research Inst.) In AGARD Electromagnetic Noise Interference and Compatibility. Nov. 1975, 14 p. refs. (For availability see N76-18256 (27-32).

The use of programmable calculators is suggested for making electromagnetic compatibility calculations conveniently and economically. Programmable calculators are available at prices ranging from about \$800 to \$5000. Programs recorded on magnetic cards or tapes for use with the popular U.S. makes of calculators will be available from the Department of Defense. Electromagnetic Compatibility Analysis Center (ECAC) in 1975. Detailed explanations of several of the ECAC programs are given to illustrate the kinds of calculations that can be performed and to indicate the ease with which the programs can be used Guidelines for the selection of calculators, and the pros and cons of using them are given.

APPLICATION OF MARKOV CHAIN THEORY TO THE MODELLING OF IFF/SER SYSTEMS

Stephen J. Sutton (IIT Research Inst.) and C. Wayne Ehler (IIT Research Inst) In AGARD Electromagnetic Noise Interference and Compatibility Nov 1975 23 p. refs (For availability see N76-18256 07-32)

The automated IFF/SSR prediction model was constructed around the Markov chain models. Inputs to the prediction model include the interrogator environment and an air traffic deployment for a specific geographic area. For each transponder in the duployment the model determines those interrogators whose signals are received, calculate the transition probabilities, selects the proper Markov chain, and calculates transponder performance parameters. These parameters are then used to calculate the performance of a selected interrogator system. To gain confidence in the model predictions, results were compared with predictions from a previously validated simulation and with available measured interrogation and suppression arrival rates. The comparison showed that the IFF/SSR model predictions correlated well with both the other predicted data and the measured data. The results of this paper show that the IFF/SSR prediction model with Markov chain transponder models provides a powerful, flexible, reliable, and accurate analysis capability.

COMPUTER GENERATION OF AMBIGUITY SURFACE FOR

RADAR WAVEFORM SYNTHESIS

R. J. Morrow and G. Wyman In AGARD Electromagnetic Noise Interference and Competibility Nov. 1975 11 p refs (For availability see N76-16256 07-32)

Recent advances in the field of surface acoustic devices are likely to encourage the implementation of complex forms of matched filter reglars. As a consequence, the system designer and EMC Analyst will require convenient methods establishing the likely system performance obtained from the various forms of signal processing. One well established technique used to determine the theoretical performance of matched filter or correlation receivers is through the application of the ambiguity function. This function has wide application as it may be employed to evaluate the theoretical received signal response in both the time and Dopoler domains. As this function handles both matched and unmatched signals it provides a convenient method of assessing both the design and eventual electromagnetic compatibility of the system. With these considerations in mind a general computer method of solving the ambiguity function has been developed and is described in this paper. Author

ANT, WNA-TO-ANTENNA EMC ANALYSIS OF COMPLEX AIRBORNE COMMUNICATION SYSTEMS

William L. Dillion In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 16 p ref (For availability see N78-16256 07-32)

Methodology and applied techniques for antenna-to-antenna electromagnetic compatibility analysis of complex airborne communication systems are presented Potential interference modes and system isolation factors are examined in conjunction with a typical equipment complement. A method of analysis is discussed which uses computer calibrated antenna space isolations with conventional analysis techniques. Some typical analysis results are presented in summary form. Antenna isolation is ciscussed as a limited factor for EMC optimization. The results of past analysis clearly show the need for frequency management to effect interference control as an integral part of the antenna toantenna EMC profile of complex airborne systems.

ANALYSIS OF THE NOISE AND ITS INFLUENCE ON COMMUNICATION SYSTEMS [ANALYSE DIJ BRUIT ET DE SON INFLUENCE SUR LER SYSTEMIS DE COM-MUNICATION)

Roger Gouillou In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 7 p. refs. In FRENCH; ENGLISH summary (For availability see N76-18258 07-32)

The paper aims at providing the communications engineer with guidelines in view to minimize the loss of information through signal reception and processing, by keeping to a minimum the

introduction of noise at the different stages of data treatment It summarizes, from this point of view, the many theoretical works found in the literature, and emphasizes the practical steps leading to the results. Noise and signal are considered through their respective spectral representations. This permits, through well known concepts, a definition of the effect of signal masking by the noise, and the calculation of the noise level as a function of processing means. Formulas established this way are easily applicable to various practical cases. Problems raised by the discovery of the signal within the noise are also mentioned.

N75-15283 Rome Air Development Center, Griffiss AFB, N.Y. COMPUTER MODELING OF COMMUNICATIONS RECEIV-ERS FOR DISTORTION ANALYSIS

J. F. Spins and D. D. Weiter (Syraguse Univ.) In AGARD

Electromagnetic Noise Interference and Compatibility Nov. 1975 p (For availability see N76-16256 07-32)

Details of an analysis technique and companion computer program are presented that have application in the area of design and analysis of electronic circuits. Particular emphasis is placed upon the application of the program to the modeling of nonlinear distortion effects in communication receivers. A discussion of moderately nonlinear systems and the treatment of such systems using the nonlinear transfer function approach is followed by circuit analysis as a potential tool in designing and evaluating circuits from an electromagnetic compatibility point of view. An overview of the computer program in terms of some of its more salient features is provided.

COMPARATIVE ANALYSIS OF MICROWAVE LANDING
SYSTEMS WITH REGARD TO THEIR SENSITIVITY TO
COMERENT INTERFERENCE

Borje Forsseli In AGARD Electromagnetic Noise interference and Compatibility Nov. 1975 8 p (For svailability see N76-16258 07.32)

Proposed landing systems were computer simulated to examine their behavior in a realistic multipath environment. Models of airfields were elaborated and the reflected and direct signal components were used as inputs to mathematical models of the receiving systems to compute the resulting position errors. This study showed that it would be possible to use groups of synthetic interference components for the same purpose. By carefully choosing the distribution of the coherent interference, the significance of the comparison can be improved and the amount of work reduced.

THE CROSSED-DIPOLE STRUCTURE OF AIRCRAFT IN AN ELECTROMAGNETIC PULSE ENVIRONMENT
Robert W. Burton In AGARD Electromagnetic Noise Interference

and Compatibility Nov. 1975 15 p refs (For availability see N76-16256 07-32)

The crossed dipole receiving antennas has been used as a representative model to approximate electromagnetic pulse effects on aircraft. Electromagnetic properties of the crossed dipole receiving unterma illuminated by a monochromatic source are considered. Results are presented for electrically moderately thin structures. In practice, when a crossed dipole receiving antenna is excited by a broad spectrum electromagnetic pulse, certain important electrical resonances occur; that is, at specific single frequencies of excitation some portions of the structure can support large amplitude standing waves of current and/or charge. Under such conditions a current maximum/charge minimum, current minimum/charge minimum, or current minimum/charge maximum may occur at the junction region. Examples of resonant and antiresonant situations for the parasitic monopole and the crossed dipole which highlight the possible interactions between the arms of the crossed dipole are presented which give insight into methods of analyzing aircraft in an electromagnetic pulse environment.

DIGITAL DATA TRANSMISSION IN AIRCRAFT EMC-PROBLEMS AND POSSIBLE SOLUTIONS

H. Rode In AGARD Electromagnetic Noise Interference and Competibility Nov. 1975 10 p (For availability see N76-16256

In the use of digital systems in aircraft, where a great deal of interference emission and very sensitive equipment are concentrated in a small space, new problems can arise due to the special type of emission and susceptibility of the digital systems. Great care must therefore be laid on the selection of the cabling (twisting rate, shielding), the line drivers and receivers, the rise and fall time, and the transmission rate. To prove in practice the meaning of theoretical evaluations of a choice of line drivers, line receivers and cables, special tests were performed on EMC test facilities. These tests also covered the different shielding and earthing possibilities. Special EMC tests were established to prove the compatibility of the digital systems with the complete alteraft system.

GENERATION AND EFFECTS OF CONDUCTION AND
RADIATION NOISE VOLTAGES BETWEEN THE COMPONENTS OF A SINGLE SYSTEM [GENERATIONS ET EFFETS
DES TENSIONS PARASITES DE CONDUCTION ET DE RAYONNEMENT ENTRE ENSEMBLES D'UN MEME SYS-TEME

A. Quidet In AQARD Electromagnetic Noise Interference and Compatibility Nov. 1975 14 p in FRENCH (For availability see N76-16256 07-32)

The main interference effects between the various components of electronic airborne systems were discussed, with emphasis on protection techniques and policies that should be adopted In recent years, the introduction of digital numerical techniques, despite their numerous advantages, have complicated the integration of components using these techniques. Protection policies against such interferences rest on the following objectives: (1) limitation, insofar as possible. In the number of static noise generators, (2) reduction of the undesirable coupling effects, (3) avoiding perturbing effects by selecting appropriate techniques for data transmission. In addition, airborne system components are requisted by certain standards and specifications such as AIR 510 C fourth edition of 15 Feb. 1983, Mil Std 461 A of 1 Aug. 1968, Mil Std 462 of 31 July 1967.

N76-16289 Siemens A.G., Munich (West Germany). THE REDUCTION OF ELECTROMAGNETIC COMPATIBILITY DUE TO NON-LINEAR ELEMENTS AND UNINTENDED RANDOM CONTACTING IN THE PROXIMITY OF THE ANTENNA OF HIGH-POWER RF-TRANSMITTERS

K. Landt In AGARD Electromagnetic Noise Interference and Compatibility Nov 1978 10 p refs (For availability see N76-16256 07-32)

With the aid of selective filters it is possible to almost completely eliminate harmonics, spurious emissions and widehand interfering signals on the output of RF transmitters, even those operating at very high output powers. These interfering signals are again generated, if nonlinear junctions or unintended random contacting create secondary radiation sources in the proximity of the transmitting antennas. The problems indicated are discussed with reference to an example for the installation of a UHF-unit and an avionic device in an aircraft, as well as on the example of an installation unboard a ship.

MEASUREMENT OF INTERWIRING COUPLED NOISE
B. Audone and L. Bolla /n AGARD Electromagnetic Noise
Interference and Compatibility Nov. 1975 13 p refs (For availability see N76-16256 07-32)

One of the major problems arising in the electromagnetic compatibility analysis of a complex system such as an airplane is the wiring interconnecting the equipments. A large amount of interference is plaked-up among cables in the same loom when, due to limited available space, emitting and sensitive wires are not sufficiently separated. A test method to measure the coupling interference and susceptibility in different load configurations (open or short circuit) is proposed with the advantage of having a realistic simulation of the wiring coupling mechanism and valid guidolines for a better cable separation philosophy.

N76-16293 Gerioa Univ. (Italy) ON THE EVALUATION OF MAN-MADE ELECTROMAGNET-IC NOISE INTERFERING WITH COMMUNICATIONS IN THE E. L. F. RANGE

Glorgio Tacconi In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 18 p. refs (For availability see N76-18256 07-32)

The mechanics of some aspects of the man made electromagnetio noise at the E.L.F. are examined that are the most favorable for propagation in dissipative media. In particular, the noise is considered as generated by a moving ship in the vicinity of an electromagnetic sensor immersed in the sea. Mathematical and experimental approaches for an estimation of such noise are proposed. Some experimental results obtained in the Tyrrhenian see are shown in accordance with theories and experiments. Local natural background noise as well as nearly and far off man made noise are considered in the context of a general transmission channel.

DESIGN OF A COMMUNICATIONS TEST (TEMPEST) RECEIVER FOR MAXIMUM BROADBAND DYNAMIC

J. B. Hager, J. C. Jones, and J. R. VanCleave. In AGARD Electromagnetic Noise Interference and Compatibility Nov. 1975 8 p (For availability see N76-18256 07-32)

in any receiving system, but especially in communications test receiving systems, dynamic range is a key parameter A particularly difficult receiving frequency range is 1 kHz to 1 MHz, where unshielded ambient noise intensity is very high, and adequate sitisfding is imprantical. In a high noise ambient, the receiving system sensitivity becomes equal to the ambient level minus the receiving system dynamic range, which is invariably higher than KTB (thermal) noise. The design of a receiver for maximum performance in detection of broadband signals is algorificantly more stringent than that of narrow band signals, and requires the techniques described in this paper, importance is placed on successive filtering of the receiver channel and maximizing signal handling capability. The related considerations concerning focal oscillator rejection for maximization of tuning range and equipment shielding are also presented.

AMPLITUDE SCINTILLATION OBSERVATIONS AND SYSTEMS APPLICATION

Herbert E. Whitney and Jules Aurons. In AGARD. Radio Systems and the lonosphere 1976 16 p refs (For availability see N76-20302 11-32)

For the design of a transionospheric communications link, scintillation data are to be reduced to statistical descriptions during those intervals for which there is stationariness of the rms fluctuations of the signal. The fade statistics are useful in chonsing coding and/or time diversity techniques to overcome this fading. Signal statistics of this type are illustrated using data recorded at equatorial, sub-suroral, and auroral latitudes. These signal statistics are folded into a morphological pattern which contains statistics of scintillation fading as a function of geomegnetic latitude, instantaneous magnetic excursion, and local time. Recent data taken at auroral and sub-suroral latitudes have shown the effects on F layer irregularities of magnetic storms. In particular, the magnetic storms of August 1972 illustrate worst case scintillation levels. Data during the storm of Oct. 31 -Nov. 1, 1973 are used to show the correlation of scintillation with local magnetic variations.

SIMULATION AND IMPLEMENTATION OF A MODULATION SYSTEM FOR OVERCOMING IONOSPHERIC SCINTILLA-TION FADING

Allen L. Johnson In AGARD Radio Systems and the lonosphere 1975 5 p refs (For availability see N75-20302 11-32)

fonospheric sointillation has been recognized as a major problem in VHF/UHF satellite communication systems. An extensive computer simulation was done in an attempt to find an economical coding-interleaving combination which could be implemented for an airborne VHF/SHF SATCOM system. A variety of coding techniques were investigated. An actual ionospheric scintilization signal was recorded and digitized for the usu in the simulation. The various coding intercaving techniques were played through this simulated channel; the results of each combination were tabulated. It was decided to implement a complete 75 bit-per-second teletyps modem utilizing the results of the simulation. The modem being built utilizes frequency shift keyed modulation. In order to operate the encoder and interleaver, a received data clock is needed. It is derived by sampling the input data and incrementally shifting a reference block until the best fit is achieved between the reference clock and a number of bits of the incoming data. This data clock is then used for timing the interleaver and encoder.

TRANSIONOSPHERIC EFFECTS ON RANGE MEASURE-MENTS AT VHF

Roy E. Anderson In AGARD Radio Systems and the lonosphere 1975 14 p refs (For availability see N76-20302 11-32)

A fully integrated satellite ranging system for locating ships was implemented at VHF. Performance of the system was examined to determine the effects of ionospheric group delay on the accuracy of the position fixes. Several 24-hour periods of ranging from a geostationary satellite to a widespread network of transponders yielded data on diurnal variations in delay and estimates on residual errors when lonospheric models are applied to the measurements. Some data on correlation distances in the longsphere were obtained. The results suggest that a VHF position fixing system using two geostationary satellites could be operated with an accuracy better than 1 nautical mile when the lonosphere is not disturbed.

N76-20308 Army Electronics Command, Fort Monmouth, N.J. Communications/Automatic Data Processing Lab. PLASMASPHERIC CONTRIBUTION TO GROUP-PATH-DELAY OF TRANSIONOSPHERIC SATELLITE NAVIGATION

H. Solcher In AGARD Radio Systems and the lonosphere

1976 15 p refs (For availability see N76-20302 11-32) A satellite navigation concept requires measurement of the time delay that satellite-emitted signals experience when traversing the distance between satellite and user. A pulse propagating this distance is slowed somewhat by an amount which is dirently proportional to the total number of free electrons (TEC) along its path. For high orbit satellites, TEC includes the lonospheric as well as the plasmaspheric electron contents. The Radio Beacon Experiment (RBE) aboard the ATS-6 satellite examined the ionospheric content, N sub I (by the Feraday technique), the total ionospheric and plasmaspheric contents, N sub T (by the group delay technique), and the plasmaspheric content (N sub T - N sub I). N sub p. Although diurnal, day-today, and seasonal variations of N sub p were observed, they were much smaller than corresponding variations of N sub I and N sub T. The ratio of plasmaspheric to conospheric contents varied diurnally, seasonally, and from day-to-day. The diurnal variation exhibits besically a nearly constant night behavior and a much lower day behavior with rapid changes just after local sunrise and just after local sunset.

IONOSPHERIC RADAR RANGE ERROR CORRECTION BY INCOHERENT SCATTER-FARADY ROTATION TECHNIQUE

George H. Millman and Glenn M. Reinsmith In AGARD Radio Systems and the lonosphere 1976 13 p refs Sponsored by RADC (For availability sea N76-20302 11-32)

The incoherent scatter phenomenon in conjunction with the Faraday effect is evaluated as a technique for near real time correction of ionospheric reder range error. The study was performed utilizing a simulator computer program, the major components of which consisted of a time variant three dimensional electron density model and an earth magnetic field model expressed in terms of a series of spherical harmonics. Theoretical estimates of the Faraday polarization angle and the incoherent backscatter power are made for an assumed high powered radar located in the mid-latitudes with the antenna beam oriented in various azimuth elevation angle configurations. Radar range bias errors derived from the incoherent scatter and Faraday rotation simulated data are compared with the true reference errors. An evaluation is given of the residual range errors, i.e., difference between the predicted and true errors, computed for the months of June and December and sunspot numbers of 10 and 60

LONG RANGE VHF TRANSEQUATORIAL FOR THE EUROPEAN-APRICAN PATH, A REVIEW OF TIME DELAY MEASUREMENTS

Michael Anastassiadis and George Stefanou In AGARD Radio Systems and the lonosphere 1976 22 p (For availability see N76-20302 11-32)

Five years of measurements of time delay of VHF signals transmitted from Athens and received at Roma (Lesotho) and later at Salisbury and retransmitted by a triggered device back at Athens, support the mechanism of a supermode propagation. The shape of time delay curves during presunset and aftersunset hours are explained on the basis of a simple geometrical model taking into consideration the height of reflecting layers in both hemispheres, the elevation angles, and the central angles between the points of emission and the points of reflections all of which affect the time of propagation of the amitted wave. The influence of thermospheric winds is also considered particularly for the axclanation of lengthening during early evening hours. From all above experiments, the exect magnetic conjugancy seems to be of minor importance, and rather large areas

surrounding the conjugate point, are regions of high interest, permitting the realization of good communication systems on 30-90 MHz band with a very low peak radiated power. Author

A NEW COMPUTER-BASED METHOD OF HE SKY-WAVE SIGNAL PREDICTION USING VERTICAL-INCIDENCE IONOSONDE MEASUREMENTS

A. Bradley In AGARD Radio Systems and the Innosphere 1976 16 p refs (For availability sec N76-20302 11-32)

A knowledge of lonospheric propagation modes and signal strengths is important for the successful operation of HF point-to-point communication circuits and over-the-horizon radars. Predictions use representations of the state of the ionosphere based either on long term trends in past ionospheric data, or on near real time ionospheric soundings at vertical incidence or over oblique paths. A new prediction scheme is described which can be used with either foregast values or direct measurements of the standard ionospheric characteristics derived from vertical incidence soundings, its important features include an improved model of the vertical distribution of electron concentration, a homing procedure to determine the rays which travel between specified terminals, an allowance for the fodusing of rays with low elevation angles, an expression for ionospheric absorption based on the lonospheric characteristic foE and the inclusion of the effects of polarization coupling loss determined in terms of ray path and magnetic field geometry.

ROWER FREQUENCY PROPAGATION ON AN 8,000 km

TRANSEQUATORIAL NORTH SOUTH PATH

H. G. Moeller In AGARD Radin Systems and the lonosphere

1970 7 p refs (For availability see N76-20302 11-32)

Two prediction improvements are suggested according to sweep frequency observations between Tsumeb, South West Africa and West Germany, in summer daytime the observed MOF is up to a factor of two higher then the predicted MUF. This error can be reduced to a factor of 1.2 if an Es-transmission factor of 7 is applied instead of a factor of 5 which had been used hitherto. In the existing predictions for long distance medium wave propagation only E-layer reflections are taken into account. in contrast to this assumption strong F-layer reflections have been observed. The median F-layer LOF was 1.3 MHz after midnight. At these low frequencies, signals reflected at the E-layer were quite often weaker than the signals reflected at the

AN IDNOSPHERIC STORM MODEL USED FOR FORECAST. ING

W. Barday In AGARD Radio Systems and the lonosphere 1976 B p refs (For availability see N76-20302 11-32)

Long term, monthly or seasonal, predictions are prepared in advance for both point to point and mobile communications requirements. Such predictions are intended to be used for planning and for contingencies and are not intended as an accurate guide for day to day operation. Forecasts prepared a few hours In advance and distributed rapidly can be used to inform the operators how the operational frequency band on a particular day differs from that shown in the long term predictions. The relationship between solar events and radio communication frequencies is incorporated in an ionospheric storm model in order to produce an acceptable forecast from the data received.

TECHNIQUES FOR REAL-TIME HF CHANNEL MEASURE-MENT AND OPTIMUM DATA TRANSMISSION George Barry and Robert B Fenwick In AGARD Radio Systems and the lonosphere 1976 10 p (For availability see N76-20302

Ì

ľ.

The time variability of path loss, noise, interference, and dispersion which characterize an HF channel can be overcome by adding three elements to the conventional communication system (1) a transmission test set; (2) an interference monitor; and (3) high order time diversity. The transmission test set continuously monitors the circuit loss and multipath, 3-30 MHz The optimum operating frequency is obvious from the test set display, but the specific frequency must be selected from among the allocated choices on the basis of interference. The interference monitor measures and stores the percentage occupancy of all HF channels and the operating frequency is chosen from the monitor display. Although a clear, propagating frequency is selected, noise and fading cause data transmission errors; the most effective solution is high order time diversity.

N78-20318 Admiralty Surface Weapons Establishment, Portsmouth (England) CHANNEL ESTIMATION TECHNIQUES FOR HE COM-

MUNICATIONS M. Darnell In AGARD Radio Systems and the lonosphere 1976 11 p refs (For availability see N76-20302 11-32)

Channel estimation is a term used to describe the process of monitoring and measuring selected parameters of a communications channel with the aim of describing quantitatively the absolute or relative states of a given set of communications channels. This information can then be employed to optimize use of the dispersive, time variable HF propagation medium. The paper discusses the philosophy and applications of estimation techniques. Three basic classes of channel estimation systems are defined and the most important practical implementations of these basic classes are described.

SHIP-SHORE COMMUNICATION AT SHORT RANGES L. W. Bardlay In AGARD Radio Systems and the lonosphere

1976 15 p rels (For availability see N76-20302 11-32) Communication between ship and shore, when the ships are sailing in coastal waters, is usually conducted in the VHF band for very short ranges and at MF and low HF frequencies. up to say 4 MHz, for ranges up to several hundred miles. MF propagation is essentially by the ground wave mode but the addition of sky wave modes at night increases the potential coverage area, increases the interference levels in the MF band and creates an interference zone where the ground and sky waves are of comparable amplitudes. The ground wave propagetion mode is assessed by taking account of system parameters, of propagation and noise characteristics and of the distance of the shore station from the coast. The optimum frequency for ground wave communication, for a particular system is indicated. The effect of sky wave propagation on the conclusions reached is also discussed. The results of some experimental work are presented which show that, for communication quality SSE telephony, operation may be extended through the fading zone. Author

W. Jewett and R. Cole in AGARD Radio Systems and the lonosphere 1976 13 p refs (for availability see N76-20302

Source encoding techniques for narrowband digital voice generate a number of PCM symbols that represent different weight functions. The relative weights of the bits/symbols are considered in the optimization of the communication circuit. This minimizes the effect of transmission errors on the synthesized speech. Thus, the channel encoding selectively adds redundancy to the signal to maximize protection to portions of the digital source signal. This is the approach that is being followed to determine the optimum characteristics for a voice processor/HF modern.

HF TRANSMISSION OF NUMERICAL DATA [TRANSMIS-SIONS NUMERIQUES SUR VOIES HE

C. Dechaux and J. M. Lebidois In AGARD Radio Systems and the lonosphere 1976 16 p. in FRENCH; ENGLISH summary (For availability see N76-20302 11-32)

In the field of digital transmissions, the major characteristic of the ionosphere is that it behaves as a multipath propagation medium. This paper describes a type of 1,200 bits/s - MODEM fitted to that kind of transmission medium and which is to be used for SSB radio transmission. After a short introduction about data transmission on HF channels, the MODEM operation mode and its implementation are reviewed; to conclude, the MODEM real life experiment results are disquised.

FEASIBILITY STUDY OF A HF ANTENNA WITH ELLIPTICAL POLARIZATION USED FOR TELEGRAPHIC TRANSMISSION WITH VERY HIGH SPEED (POSSIBILITES DE REALISATION ET D'EMPLOI D'UNE ANTENNE A POLARISATION ELLIPTIQUE DANS LA BANDE H, F, POUR UNE LIAISON

ELLIPTIQUE DANS LA BANDE H. F. POUR UNE LIAISON A GRANDE VITESSE TELEGRAPHIQUE!
R. Hanbaba and J. C. Zehren In AGARD Radio Systems and the lonosphere 1976 18 p. refs. In FRENCH (For availability see N76-20302 11-32)

The design of an HF antenna radiating, in a given direction, a wave with elliptical or circular polarization was considered. The radiating system consists of two intersecting half-wave dipoles with an angle 2 beta between them, and located in a plane inclined at an angle alpha to the vertical. The effect of the finite permittivity of the ground on the directivity diagram was analyzed, and the gain was computed with the type of polarization considered. The fessibility of obtaining an elliptical polarization with a fixed vector orientation was then studied as a function of the current fed to each dipole. Finally, a numerical application was presented for a frequency of 10 MHz, including the computation of the soil coupling impedances. Transi. by Y.J.A.

N76-20326 Max-Planck-Institut fuer Aeronomie, Lindau Über Northeim (West Germany). INFLUENCE OF SPREAD-F ON HF RADIO SYSTEMS

J. Roettger In AGARD Radio Systems and the lonusphere 1978 19 p. refs (For availability see N78-20302 11-32)

Fading power spectra and amplitude distributions of transequatorial HF signals are evaluated. The special type of ionospherio transhorizon radar which is applied for these investigations locates side reflecting spread-F irregularities in the equatorial ionospheric By means of the digitized data, the characteristics of TEP signals, which are strongly influenced by the side reflecting equatorial spread-F irregularities, are determined. Considerable pulse dispersion is observed. Strong flutter fading is evident during spread-F conditions. The fading power spectrum and the amplitude distribution of the TEP signals is calculated from the observational data and matched to a Nakagami-Rice distribution. The parameters obtained from this data reduction state that strong electron density gradients in the irregularities give rise to side reflection of HF signals. Effective radar cross sections and the mean conservation time of irregularity structures are calculated from the amplitude evaluation.

APPLICATION OF PSEUDO-ORTHOGONAL CODES TO TRANSMISSION THROUGH THE IONOSPHERE [UTILISATION DE CODES PSEUDO-ORTHOGONAUX ADAPTES AUX TRANSMISSIONS IONOSPHERIQUES]

F Chavand, M Gindre, and C Goutelard In AGARD Radio Systems and the lonospure 1976 24 p refs (For availability see N78-20302 11-32)

The application of pseudo-orthogonal codes to signal transmission through the ionosphere was considered so that the receiver characteristics need not be modified permanently as a function of this transmission parameters. The pseudo-orthogonality of those codes was defined and discussed. The code parameters were determined from the propagation

characteristics and their random variations. An optimization technique was used in this regard, taking into account the propagation and receiving conditions. Families of codes were obtained and their validity confirmed by experimental results. The date rate that may be reached corresponds, in some cases, to a gain of 25, with a better protection against disturbances and allowance for error corrections.

B J. Burdick, J H. Chiaholm, and B E. Nichols. In AGARD Radio Systems and the lonosphere. 1976. 18 p. refs. Sponsored by ARPA (For availability see N75-20302. 11-32).

An experiment to investigate the polar ionosphere was undertaken during the period November 1971 through November 1972 with an HF radar stationed in Northern Maine, U.S.A. operating on a regular schedule collecting backscatter data over a 90 deg azimuthal sector of the polar ionosphere and monitoring beacons located at Keflavic, Iceland and at Thule and Narearssuag, Greenland, From this data base, a daytime and a nighttime period were selected for ionospheric modeling and raytacing analysis. The structure of the nighttime ionosphere was determined from simultaneous radar, beacon and airborne ionosphere measurements and was found to include the F-layer trough, plasma ring and auroral E-layer. On the basis of the radar backscatter and beacon data alone, the structure of the daytime ionosphere was found to be consistent with a one dimensional model.

11-32)

A.H.F. backscatter sounder located at Valensole (44 d.g.N: 6 deg E), coupled to a wide band highly directive antenna with a caspolity of six discrete radiating directions on each side of the geographic north, recorded in 1972 and 1973 frequent occurrence at night of irregularities located in the high latitude ionsophers (latitude 55-85 dayses). Interpretation of the data using ray tracing techniques showed that field aligned irregularities often occurred simultaneously at low sititudes (240-280 km) and above the Firegion maximum (340-400 km). A swept azimuth recording is produced showing at a given time a wide extension in lange of the irregularities. A series of recordings was made under conditions of high magnetic activity, showing a displacement towards the equator of the zones of occurrence of irregularities. The displacement is about 2.1 degrees in latitude per unit Kp.

FORMATION AND MOVEMENTS OF IONOSPHERIC IRREGULARITIES IN THE AUROMAL E-REGION
Alv Egeland In AGARD Radio Systems and the lonosphere
1976 15 p. refs (For availability see N76-20302 11-32)

The auroral E-region undergoes more or less continuous, unpredictable, structural ionization changes of almost all scales of size and time. These ionospheric irregularities, with rapid motions and oscillations, are superimposed on the large scale. long term variations in the medium. The irregularities will change the propagation conditions and degrade radio communication and radar performance. The ionization structures also upset the delicate energy balance in the upper atmosphere by changing almost every parameter which specifies normal conditions. Formation and movements of small scale irregularities in the auroral E-region are reviewed. A variety of instability concepts, which may explain the production of ionization irregularities, have been postulated. Some of these will be mentioned and compared with recent ground and in-situ measurements. In addition, macroscopic drift motions in the E-region of ionization irregularities will be summarized. High Resolution Measures Ments of Time DeLay
AND ANGLE OF ARRIVAL OVER A 911 km HF PATH
D. W. Rice In AGARD Radio Systems and the lonospere
1976 18 p refs (For availability see N76-20302 11-32)

The results of some 40 hours of afternoon and evening measurements of HF propagation over a 911 km path are presented. An FMCW sounding technique was employed with a linear receiving array of 1.2 km aperture. These arrangments made it possible to resolve modes differing in time of arrival by as little as 20 microseconds, and to determine the angle of arrival of each mode. The results show that markedly nonlinear phase fronts can occur even for apparently single modes of propagation, as a result of the irregular structure of the knosphere which splits the signal into a number of sub-modes. This finding presents a possible limitation to the accuracy of HF direction-finding, which applies even to systems capable of resolving the modes

Traveling ionospheric disturbances (TIDs) produce changes in the bearing of the signals received from a distant transmitter vis the ionosphere By monitoring the Doppler frequency shifts in the reflected signal at three or more receiving sites the speed, direction and magnitude of the TID can be determined if the Doppler frequency shift at the direction finder is also measured. the displacement of the reflection point and hence the bearing deviation produced by the TID can be calculated. A very considerable improvement in accuracy is obtained when such corrections are applied to signals propagated over an 850 km

N74-31668 Naval Electronics Lab. Center, San Diego, Calif. CONFORMAL ARRAYS FOR AIRCRAFT

J. Provencher, J. Boyns, and A. Hessel (Polytechnic Inst. of New York) In AGARD Antennas for Avionics Jun. 1974 15 p refs (For availability see N74-31667 21-09)

Design consideration involved with the multifrequency conformal array are: (1) element pattern effects in non-planer arrays. (2) multifrequency array techniques; and (3) MIC components and cost considerations. The element patterns of conical arrays are examined to determine if behavior is similar to known element patterns for the cylindrical or planar arrays and a conical sector experimental array is used to simulate selected scanned beam positions to determine array behavior, i.e., beamwidth, scan timits, polarization and side tobe level. The concept of the multifrequency array has been shown to be feasible. and the use of the interlacing technique with the conformal array allows more flexibility due to the larger element spacing possible. These features, combined with MIC hybrid matrix techniques for multiple beams, diode phasors and hybrid drivers for heam steering, and flush mounted radiating elements provide the system designer with a versatile antenna system. Prototype arrays designed at wavelengths of 30cm, 10cm, 7cm and 3cm are described.

N74-31669 Naval Research Lab., Washington, D.C.

PATTERNS AND POLARIZATIONS OF SIMULTANEOUSLY EXCITED PLANAR ARRAYS ON A CONFORMAL BUR-FACE

J. K. Halso and A. G. Che. In AGARD. Antennas for Avionics Jun. 1974 16 p. refs (For availability see N74-31667 21-09)

A conformal array on a surface of small curvature can be approximated by a number of planar arrays, several of which may be excited simultaneously so as to achieve a purformance similar to that of a conformal array. Since the main beam of a planar array can be steered to any direction in visible space, several arrays, each oriented in a different direction, can be steered cooperatively to form a single beam in a desired direction. A general formulation of the radiated field of such an array of arrays is developed with the aid of formulas which relate the components into which a vector is resolved in one orthogonal coordinate system with those into which the same vector is resolved in a second orthogonal coordinate system. Using this formulation, it can be shown that within each array, the conventional row and column phase setting can be used. As examples, the radiation patterns and polarizations of multiple arrays of short dipoles are studied using the present formulation. A comparison of the multiple planar array with the conventional conformal array is also presented.

DESIGN OF PERIODICALLY MODULATED TRI-PLATE ANTENNAS

Finn Laureen In AGARD Antennas for Avionics Jun. 1974 6 p refs (For availability see N74-31667 21-09)

A new configuration of periodically modulated traveling wave tri-plate antennas has been developed. The physical complexity of this new configuration implies that sufficiently accurate design data are extremely difficult to predict by any known analytical methods. Three different measuring methods to achieve experi-mental design data are discussed. The far field method, which has been further developed during this investigation, the near field method, and the insertion loss method. The most appropriate combination of the three methods is used to find the design data. An X-band antenna array is designed and discussed. The new structure is mechanically simple, it has good impedance characteristics, allows good control of the sperture illumination, and radiates a linear polarized field with a very low cross polarized

N74-31671 Ferranti, Ltd., Edinburgh (Scotland) HIGH EFFICIENCY ANTENNAS FOR AIRBORNE RADAR R. W. Forrester and A. J. Lait. In AGARD. Antennas for Avionics Jun. 1974 9 p. refs (For availability see N74-31667 21-09)

Consideration is given to ontenne types which are suitable for use in airborne raders, and their advantages and disadvan-tages discussed. Several important antenna properties are efficiency, sidelobe level, scanning rate, weight, cost, etc. Emphasis is concentrated on methods which give a high antenna efficiency, whilst trying to maintain as many of the other properties as possible. An experimental Cassegrain antenna has been designed and built. It employs energy redistribution techniques to give a high efficiency, whilst retaining a reasonable sidelobe level. A measured efficiency of 70% was obtained at the design frequency, which only dropped to 65% at 600 MHz above design frequency. The antennas gave good sum and difference patterns over a 2 GHz band in X-band. Author

ANTENNA J. P. Grabowski and F. L. Lanphear In AGARD Antennas for

Avionics Jun. 1974 12 p refs (For availability see N74-31667 21-OB)

The high power SHF antenna, which is mounted atop the fuselage of a KC-136 aircraft, is part of a link which permits communication between tactical terminals by means of a synchronous sititude satellite. The antenna can acquire and track a satellite beacon signal, hold a stable line of sight for a short period of time, and is capable of being computer pointed. The antenna configuration was specifically designed for har-dling high CW power levels at X-band frequencies without the use of forced air or liquid cooling. A 32-inch Cassegrain antenna system was selected to provide a minimum antenna gain of 32.5 db over a 5% transmit frequency band and a separate 5% receive frequency band. The antenne radiates a right hand circularly polarited signal at a CW power level of 12.5 kW and simultaneously receives left hand circularly polarized signals. Computations utilizing measured antenna patterns indicate the antenna noise temperature to be 84 K. The feedhorn is a simple conical horn aperture operating in the dominant mode. A 2-mil H-film aperture window serves as the feed radome and pressure barrier. Compactness is achieved in the feed design by incorporating a circularly polarized dual mode transducer which generates the required senses of circular polarization and at the same time provides the duplexing between the transmit and receive signals.

N74-31674 Royal Aircraft Establishment, Farnborough (England). RADIATION CHARACTERISTICS OF HE NOTCH AFRIALS INSTALLED IN SMALL AIRCRAFT

N. A. D. Pavey In AGARD Aittennes for Avionics Jun. 1974

15 p refs (For availability see N74-31867 21-09)

The radiation characteristics of HF notch serials in small aircraft are analyzed for the band 2 to 10 MHz. Radiation occurs in two main modes: a magnetic dipole mode resulting from the high local RF currents flowing around the notch, and an electric dipole mode resulting from longitudinal RF currents in the fuselage. A procedure is given for the astimation of the radiation

efficiency of an aircraft notch aerial. It is shown that high radiation efficiencies may be realized at frequencies near the aircraft electrical resonance, typically 10 MHz, but that a rapid reduction of radiation efficiency occurs at lower frequencies. A radiation officiency of less than 0.1% at 2 MHz is to be expected for many aircraft notch serials.

POLYROD AERIALS FOR AVIONIC APPLICATIONS

M Scorer and A. M. Smith. In AGARD. Antennas for Avionica Jun. 1974. 13 p. refs. (For availability see N74-31867. 21-09)

The effect of adding rectangular dielectric slabs, having cross sections of the order of tens of square wavelengths, to the aperture of an aerial in studied with a view to increasing its gain. A theory has been developed to describe the performance of such an aerial and has been verified experimentally. Theoretical and experimental curves of gain enhancement versus slab length for slabs having various dielectric constants are presented. Hybrid slabs, comprising sections of different dielectric constants, have been designed according to the theory and show improved performance over slabs of constant dielectric constant. Slabs excited by feeds whose opertures have cross sections smaller than the slab cross section have also been examined. Author

N74 31678 Royal Radar Establishment, Malvern (England). LINEAR PHASED ARRAY FOR YAW STABILISATION D. S. Hicks *In* AGARD Antennas for Avionics Jun. 1974 14 p. refs (For availability see N74-31867 21-09)

The theoretical performance of a linear digital phased array with both agust and unequal interelement spacing has been investigated with the aid of a computer program written in ALGOL 68R. Three aerials have been studied. The first is a conventional linear phased array in which each element consists of a waveguide horn. The alements are placed side by side to form a fully filled aperture. The other two arrays consist of identical waveguide horn elements but the spacing is not equal. Two arbitrarily chosen spacing laws were studied each of which had an exponential form. The loss in gain due to phase quantization has been calculated and the effects of the unequal inter-element

spacing law on gain and beamwidth is estimated. The beam pointing error, the beam granularity and the magnitude of the peak sidelobes are presented here for the three arrays. It is shown that some reduction in the number of elements required to fabricate an array may be achieved if the inter-element spacing is not made equal, the magnitude of the grating lobes may be significantly reduced if the spacing law is chosen correctly Lastly a simple means by which a static split system may be achieved is discussed and some simulation program results prosented.

AEW RADAR ANTENNAS

Tornos Liewelyn agRhys and Greatie Anderson Andrews, Jr. In AGARD Antennas for Avionics Jun 1974 17 p refs (For availability see N74-31667 21-09)

It is shown that the single most important factor influencing the ability of the AEW radar system to operate is the antenna's sidelobe performance. In general, this sidelobe performance is dominated by the airframe on which it is mounted. Careful design is needed, considering both aerodynamic as 'vell as electrical aspects, before an overall optimal system configuration can be determined. Once this antenna sidelobs performance has reached an acceptable level, it is then found that the next limitation is that due to errors in the compensation of platform motion. Recent advances in digital processing technique offer many advantages in connection with moving-target indication (MTI) but these can only be realized when the platform-motion compensation is sufficiently accurate. The various system considerations governing this performance are discussed and the requirements reflecting on the antenna performance described in detail Author

AIRBORNE LOW-VHF ANTENNAS
Charles E. Cooper In AGARD Antennas for Avionius Jun.

Charles E. Cooper In AGARD Antennes for Avionius Jun. 1974 8 p (For availability see N74-31667-21-09)

A blade type antenna design is considered for airborno transmission and reception, with variants covering major sections of the overall frequency band from 26 to 100 MHz. It uses miniature high vacuum relays to tune via pre-selection of up to six binary related inductors, providing up to sixty four tuning combinations, with individual band widths varying from about + or - 0.5 to 5.0 MHz. The relays are remotely controlled either manually or automatically, and the retune process can be virtually instantaneous upon both require and ready to transmit modes, without having to be incepted by any period of transmission, incorporation of a variable runing system was compelled by the specified combination of total frequency coverage and maximum allowable dimensions for the entenna. However, experimental investigations into the practical limits of broadbanding produced an anterina dealgn fixed tuned to cover 38 to 46 MHz, which is briefly described. A brief outline of a wideband VHF homing antenna which uses elements formed out of transparent metallic-film depositions upon the acrylic canopy of the Gazelle helicopter is included

N74-31681 Office National d'Etudes et de Recherches Aerospatiales, Toulouse (France). Lab. du DERMO. TE RUB 11 CIRCULAR WAYEGUIDE FERRITE PHASERS OPTIMIZATIOP:

A. M. Dupvi/ and A. C. Priou In AGARD Antennas for Avionics Jun. 1974 16 p. refs (For availability see N74-31667 21-09)

An exact analytical and numerical method has been elaborated for the complete determination of the propagating modes in a reduced size circular TE 1 waveguide partially or fully filled with a lossy axially partially magnetized ferrite rod. Computed results at 17 GHz and 9.5 GHz are presented which allow for optimization of circulary polarised phasers such as Duat Plode Phasers (D.M.P.) or Polarization Insensitive Phasers (P.I.P.).

A CROSSED-SLOT BELT ARRA, ANTENNA FOR SATELLITE APPLICATION

R. Breithaupt, B. Clarke, and D. Waung In AGARD Antennas for Avionics Jun. 1974–14 p. refs (For availability see N74-31667 21-05)

A partially complete leasibility study of the design and fabrication of a fixed beam, circular-polarized belt array for possible use as a telemetry/command antenna on a geostationary cummunications satellite, is described. This application requires a toroid

shaped coverage pattern for use when the satellite is not criented on station. The belt array of circular-polarized elements used is fed using travelling wave excitation by a thin plated dielectric waveguide of 050 in x 2 350 in, cross section. After some measurements on round hole radiating elements, crossed slots with external dielectric loading were finally chosen. These elements were matched and characterized in terms of scattering parameters in an active array environment. Measured performance of this array was less than expected due to significant effects of tolerance and placement of the external dielectric loading on individual elements.

CROSS-POLARISED RADIATION FROM SATELLITE REFLECTOR ANTENNAS

A W Rudge, T Pratt, and A Fer In AGARD Antennas for Avionics Jun 1974 9 p. refs (For availability see N74-31667 21-09)

The limited RF spectrum which is available for satellite communication systems has led to increased interest in the use of dual polarized and orthogonally polarized multiple beam antennas. Since an accurate knowledge of the antenna side-lobes and cross polarized radiation is necessary to ensure adequate isolation between RF channels, this paper examines some available techniques which can be employed to predict the vector fields of reflector antennas. The problem of providing an adequate description of the antenna primary feed radiation is found to be a critical factor. Results for predicted and measured cross polarized radiation fields are presented.

PROBLEMS OF LONG LINEAR ARRAYS IN HELICOPTER
BLADES

R. H. J. Cory. In AGARD. Antennas for Avionitys. Jun. 1974 18 p. refs (For availability see: N74-31667-21-09)

Helicopter blades offer sites for the inclusion of long microwave antennas to give narrow azimuthal beams scanned by the rotation of the blades. The variation of blade attitude as it rotates is such that it may lag, lead, bend in vertical and horizontal planes and twist, and in consequence places limits on the practical length of a linear array. The choice of location for antennas, either in the front or trailing edge, or out or inboard is discussed. Certain advantages accrue from a design where the antenna is located near the center of gravity of the blade suction, and radiating rearwards through the trailing edge, which requires to be of dielectric material. The length of the section of the trailing edge can be employed as a dielectric tapered slab antenna to shape the beam in the vertical plane and give more gain and direct the beam in a given direction. Theoretical discussion of the mechanism of this antenna and the holice of permittivity for the dielectric slab is discussed.

A COMMUTATION ON ANTENNA SYSTEMS COVERING STANDARD AIRCRAFT AND BALLOONS [SYSTEMS D'ANTENNES A COMMUTATION REALISANT UNE COUVERTURE AVION AUX NORMES AEROSAT]
C. Ancono and P. Froidure In AGARD Antennes for Avionics

C. Ancona and P. Froidure In AGARD. Antennas for Avionics Jun. 1974. 8 p. refs. in FRENCH (For availability see N74-31687 21-09)

Aeronautical satellite design, utilizing eircraft antenna systems, to assure hemispheric coverage with a minimum of gain was discussed. Throu types of systems were considered: the electric scenner network, mechanical orientation solutions, and commutable antenna systems. Several theoretical aspects of the problem including angular relations, gain of antenna axis assuring such coverage, and the minimum gain in the angular zone considered, were examined.

N74-31686 National Aerospace Lab., Amaterdam (Netherlands). A LINEAR AHRAY OF BLADE ANTENNAS AS AN AIRCRAFT ANTENNA FOR SATELLITE COMMUNICATION

O. B. M. Pietersen, J. P. B. Vreeburg, and F. Klinker. In AGARD Antennes for Avionics. Jun. 1974, 13 p. refs (For availability see N74-31667, 21-09).

In a ground-satellite-aircraft communication system the aircraft entenna is a critical part since it has to meet the typical anvironmental requirements and possess a rather high grist. This paper describes a suitable antenna system, installed on a hokker friendship aircraft. It consists of a linear array of blade antennas, a power division and phase shifting network in coax technique.

and a manual controlled beam selector/indicator. The design of the array is based on a mathematical model that has been constructed from theoretical considerations and experimental results. Mutual coupling effects are accounted for by using scattering coefficients. With the sid of a computer the spacings between the antennas were determined in such a way that a nearly constant directivity in the yaw plane of the alroraft could be expected. The performance of the array was availuated in several flights in which radiation patterns were measured in the receive and the transmit mode. From these measurements it is concluded that with the linear phased array of eight blade antennas a gen of 10 db can be achieved.

UHF LINEAR PHASED ARRAYS FOR AERONAUTICAL SATELLITE COMMUNICATIONS

H. L. Werstiuk, J. D. Lambert, L. A. Maynord and J. H. Chinnick In AGARD. Antennas for Avionics. Jun. 1974, 14 p. refs (For availability see N74-31667, 21-09)

An ultrahigh frequency phased array antenna has been developed and test flown on a Canadian Forces C-4 Dekota and a C-130 Hercules. Successful voice communications were achieved with the sircraft terminals via the Lincoln Experimental Satellite LES-6 at 300 MHz. The prototype antenna system consists of nine blade antenna elements mounted along the top of the sircraft fuselage. The antenna is electronically scanned and generates a series of symmetrical conical fan beams. The electronics necessary to control the array scan are relatively simple because of the single dimension of the array and the insensitivity of the patterns to large phase errors at each element. This paper describes the techniques used to construct the phased array, and some of the test results obtained. Two methods developed to provide automatic tracking for the array are also described.

N74-31688 Transportation Systems Center, Cambridge, Mass A COMPARISON OF TWO L-BAND AIRCRAFT ANTENNAS FOR AERONAUTICAL SATELLITE APPLICATIONS

Robert G. Bland and John M. Clarke In AGARD Antennas for Avionics Jun. 1974 24 p refs (For availability see N74-31667 21-09)

A comparison is made of the measured performance characteristics of two circularly polarized flush mounted L-band aircraft antennas for aeronautical satellite applications in order to facilitate radiation pattern measurements, the previously validated technique of using a scale model aircraft antenna was employed. One of the candidate antennas under comparison is a cavity backed dipole fod slot configuration. Measurements were conducted on a 1/10th scale model of a Convair 880 aircraft. The other antenna is an orthogonal mode crossed-slot configuration. In this case measurements were conducted on a 1/20th scale model of a Boeing 707 aircraft which is almost identical in size to the Convair 880. The basic requirements of this class of antenna are to provide moderate gain of +4 above istropic at L-band over the upper hemispheric region of the aircraft. A diversity combination technique study for the two antennas under comparison considers a switched multiple element system in which various fuselage placement and combination arrangements of elements are evaluated.

CIRCULARLY POLARIZED L-BAND PLANAR ARRAY FOR
AERONAUTICAL SATELLITE USE

Benito (falumbo and Salvatore Cosentino In AGARD Antennas for Avionios Jun. 1974–15 p. refs (For availability see N74-31667 21-09)

A circularly polarized L-hand planar array for aeronautical satellite use is presented. A simple trade-off is outlined among the several earth coverage antenna types mainly for what concerns the constraints on weight and size. From this trade-off a planar array, consisting of two interlocad arrays of transverse and longitudinal slots, appears the most attractive solution, mainly if wide operating bendwidths are not required. The design criteria critical areas together with the main technological and mechanical characteristics are discussed. The main results on an experimental work on transverse slots are reported with their implications on the antenna design criteria. Experimental results (radiation patterns, VSWR) on a breadboard and on the L-band model are presented.

N74-31690 EMI Electronics Ltd., Feltham (England). UPPER L'BAND TELEMETRY AERIALS FOR ROCKETS AND MISSILES

J Mahoney In AGARD Antennas for Avionics Jun. 1974 17 p. refs (For availability see N74-31667-21-09)

Future telemetry systems on missiles and rockets are likely to operate at upper L-band frequencies. The advantages to be gained and the problems likely to be encountered at these higher frequencies and the effects of change in the radiation pattern due to increased electrical spacing between individual serials is given for a wide range of missile diameters. Methods of improving the radiation pattern coverage by altering the phase distribution to individual aerials and/or increasing the number of serials are described. Effects caused by missile projections, i.e. wings and tailfins and surrounding structures such as launcher tubes and sirroraft fuselage upon the radiation pattern are discussed. A companion between the performance of existing telemetry serials operating at 450 MHz and various prototype upper L-band aerusis is given Problems relating to the working environmental conditions for a wide range of missile applications are de-

N74-31691 Rome Air Development Center, Griffiss AFB, N.Y. ELECTRONICALLY SCANNED TACAN ANTENNA AZ AN ENROUTE AND TERMINAL NAVIGATIONAL AID Edward J. Christopher In AGARD Antennas for Avionics Jun. 1974 11 p. refs (For availability see N74-31667 21-08)

The principles of operation of present mechanically rotated Tacan antenna systems and their performance characteristics are considered A Tacen capable of providing full band operation and eleictronic acaining in a single radiating structure is demonstrated. The array approach permits elevation pattern shaping. Through a combination of steep pattern slope at the horizon and low side lobes below the horizon, siting is less sonaltive, i.e. bearing errors over the required spacial coverage of the Tacan system, which are introduced by the antenna environment, are minimized. There are no moving parts that require preventive maintenance and modular design allow most repairs to be made in the field, reducing both mean time and mean cost to repair when compared with existing mechanical systems

N74-31692 AEG-Telefunken, Ulm (West Germany). ANALYSIS OF FINITE ARRAYS OF RECTANGULAR APERTURES ON CONDUCTING ELECTRIC COATED CYLINDERS

J. Vogt. In AGARD. Antennas for Avionics. Jun. 1974. 7 p. refs (For availability use N74-31667 21-09)

The aim of the presented theory is to investigate the influence of mutal coupling and creeping waves on the performance of a phased array antenna, consisting of a finite number of apertures flush-mounted on the surface of an infinite conducting cylinder with a concentric dielectric covering. The numerical results show that mutual effects are reduced due to the cylinderical structure of the surface, but are increased due to the dielectric covering

MICROWAVE ANTENNAS FOR HYPERSONIC MISSILES Christian Poult In AGARD Antennas for Avionics Jun. 1974 4 p refs in FRENCH, ENGLISH summary (For availability see N74-31667 21-091

Within a flight program airmed at analyzing physical phenomena during reentry of an hypersonic missile litto the atmosphere, three types of antennas were used, radiating in the S. C and X frequency bands. The type of antenna chosen (rectangular iris embedded in alumina) allowed a design satisfying particularly severe environment conditions while retaining a widely open radiation pattern, which permitted an omnidirectional pattern set, to be obtained, by a combination of sets

N74-31694 Royal Aircraft Establishment, Fainborough (England) THE DESIGN OF WIDE BAND NOTCH AERIALS AND SOME APPLICATIONS TO AVIONICS

George Bagley in AGARD Antennas for Avionics Jun 1974 9 p refs (For availability see N74-31667 21-09)

Experimental results obtained from notches of a variety of rectangular shapes out in semi-infinite metal sections are reported, and the various combinations of center frequency and impedance bandwidth which can be obtained from a notch of fixed physical length are illustrated. The results relate to notch used in the self resonant mode, without any additional lumped reactions

The variables investigated (for a fixed length notch) are notch width, thickness of the section, and feed point position. It is possible to drive the notch either as a narrow band quarter wave radiator, or as a half wave radiator with a frequency bandwidth of 2 0-1 Several possible applications are discussed. including an omni-azimuthal horizontally polarized radiator with a band width of 3 0 1

N74-31695* Jet Propulsion Lab . Calif Inst. of Tech . Pasadona DUAL FREQUENCY DICHROIC FEED PERFORMANCE

D. A. Bathker. In AGARD. Antennas for Avionics. Jun. 1974 10 p refs (For evailability see N74-31667 21-09) (Contract NAS7-100) CSCL 17B

The NASA Deep Space Net (DSN) in support of the Viking Mars Project in 1976, and for science and technology demonstrations during the Mariner-Venus-Mercury mission in 1974, has developed and implemented a dual (S- and X-band) feed for large ground microwave antennas. This feed provides for a multiplicity of functions; very low listening capability at each downlink (spacecraft-to-earth) band as well as simultaneous diplexed very high cw power uplink (earth-to-spacecraft) at the S-band frequency. Total 64-m antenna system performance, is considered in terms of gain, operating noise temperature and dual beam pointing or boresight coincidence. Because of the unique ability to fold or stow the dual band feed elements for single band operations, the performance definition between single and dual band operations will be reliable and accurate.

EMPLOYMENT OF NEARFIELD CASSEGRAIN ANTENNAS WITH HIGH EFFICIENCY AND LOW SIDELORES, TAKING THE INTELSAT-GROUND STATIONS AND THE GERMAN HELIOS-TELECOMMAND STATION AS EXAMPLES

Uwe Leupelt and Wolfgang Rebhan In AGARD Antennas for Avionics Jun. 1974 10 p. refs (For availability see N74-31687

A number of the large reflector antennas now employed by ground stations for satellite communication are constructed according to the nearfield Cassegrain technique. After a short description of the basic electrical principles involved as well as of the method of obtaining constant aperture illumination with the nearfield antenne also and thus optimizing afficiency by suitable shaping of the reflectors, a novel design for antennas of this type discussed. It allows the sidelobes of the radiation pattern to be reduced without excessively reducing gain. A special toroidal aperture illumination and a favorable arrangement of the subreflector supports are used for this purpose. The dimensions and design of the 28.5-m antennas already mentioned in connection with the Intelsat system are discussed and the 30-m antenna now under construction for the German Helios telecommand satistion described as an example for the realization of an antenna with low sidelobes. The radiation characteristics at higher frequencies and the cross-polarization properties with the aid of measured radiation patterns are illustrated.

DEVELOPMENT OF AN S-BAND DUAL MODE HORN FOR TELEMETRY RECEPTION BY THE 100 M EFFELSBERG RADIO TELESCOPE

W. Hess and B. Liesenkoetter In AGARD Antennas for Avionics Jun. 1974 8 p. refs (For availability see N74-31667 21-09)

A Gregorian antenna system with 100 m paraboloid is being equipped with a dual mode hom feed in the secondary focus to provide favorable gain and noise temperature characteristics. The limited size of the apex cabine demanded length reduction by optimizing the horn feed zone in addition a directional coupler, integrated in the horn feed zone, is developed for special test purposes. All measurements during the development period as well as the qualification tests are been carried out on a X-band scaled model. The design of the original horn feed simed in particular at cheapness, a short manufacturing period and a low weight. Thus a frame construction with non supporting inner horn structure is applied.

N74-31693 Air Force Cambridge Research Labs., L. G. Hanscom Microwave Physics Lab. Field, Mass ARRAY AND REFLECTOR TECHNIQUES FOR AIRPORT PRECISION APPROACH RADARS

Robert J. Mailloux and Philipp Blacksmith In AGARD Antennas for Avionics Jun. 1974–14 p. refs (For availability see N74-31667-21-09)

The purrent state-of-the-art among array and array/reflector antennas for limited scan coverage, is surveyed and some new array techniques for this application are introduced. Other system parameters, such as frequency selection, are discussed in light of their influence on antenna design requirements but the principle task addressed by the paper is to use the parameters of present PAR antenna systems to estimate the potential advantages of new technology. Examples cited as new technology include the use of arrays to feed dual reflectors or lenses for improved aperture efficiency and reduced array size, and the AFCRL array techniques using large multimode apertures for grating lobe suppression and pattern control. Comparisons of these types of technology are given for selected applications.

IN-FLIGHT MEASUREMENT OF AIRCRAFT ANTENNAE RADIATION PATTERNS

Helmut Bothe In AGARD Antennas for Avionics Jun. 1974 9 p. refs (For availability see N74-31667 21-09)

An in-flight measuring system which is completely independent from groundbased position finding equipment like radar and kinetheodolites. The measuring method is based on VOR (Very High Frequency Cmnidirectional Range System) and DME (Distance Measuring Equipment) information obtained onboard the aircraft. This information is telemetered together with the other necessary parameters like heading, altitude, pitch and roll angles. These parameters are used to calculate the aspect angle and the distance of the aircraft from the ground based field intensity measuring device. Real time calculation is done on a digital computer. The computer output supplies aspect angle and distance corrected field intensity as well as flight-path parameters in analog voltages for graphic presentation. After a detailed description of the measuring method and system some examples of measured patterns are shown. In addition the magnitude of possible errors in the plotted radiation patterns are discussed. Author

N74-31702 Naval Research Lab., Washington, D.C. DYNAMIC MEASUREMENT OF AVIONIC ANTENNAS

I. D. Olin and E. E. Maine, Jr. In AGARD. Antennas for Avionics Jun. 1971. 14 p. refs (For availability see: N74-31667, 21-09).

The equipment, data handling, flight control and some of the results obtained with a system specifically designed for dynamic measurements is described. The determination of sircraft aspect angle uses an approach based on measurements made the ground radar site with the aircraft flying straight line courses. Then making certain assumptions regarding flight attitude.

a proper coordinate transformation can be effected and principal plans measurements plotted. The antenna signal source is provided by a delayed beacon triggered by an illuminating radar and driving the antenna under tests. To illustrate the results patterns for a X-band installation are shown. Coverage can be provided for an azimuth profile from nose-on (0 deg) to 10 tail-on (180 deg) and for an elevation profile beam 0 deg to 30 deg below the alroration for fixed azimuth aspects of nose-on and tail-on. Angle accuracy is + or - 2 degrees and the accuracy of antenna gain measurements is estimated to be + or - db.

OFF-BORESIGHT ANGLE ESTIMATION WITH A PHASE COMPARISON MONOPULSE SYSTEM

W. Sander In AGARD Antennas for Avionics Jun. 1974
13 p. refs (For availability see N74-31667 21-09)

The problem of estimating the angle of arrival is considered for phase comparison monopulse (PGM) system in the presence of internally generated thermal noise. A maximum likelihood analysis produces the form of the estimate which does not differ essentially from that found earlier for an amplitude comparison monopulse (ACM) system. In deriving the probability density function of the estimate, no approximations of the nonlinear monopulse error curve are made. Therefore mean and variance of the estimate computed by numerical integration are valid at any signal noise-ratio and at any engle. The bias of the estimate at low and moderate SNR is higher than known by other theories. A computer simulation proves the correctness of the results. A comparison between radar and passive baseon tracking mode is made, and the problem of bidimensional angle measurement is mentioned.

INVESTIGATION OF CHARACTERISTICS AND PRACTICAL IMPLEMENTATION OF ARBITRARILY POLARIZED RADIA. TORS IN SLOT ARRAYS

J. S. Ajloka, D. M. Joe, R. Tang, and N. S. Wong. In AGARD Antennas for Avionics. Jun. 1974. 15 p. refs (For availability see N74-31667 21-09)

(Contract F19628-70-C-0142) The feasibility of obtaining arbitrary polarization in both one and two dimensional arrays of slots in dual mode bifurcated waveguides has been demonstrated. The radiating element consists of a pair of grossed slots in the sidewall of a bifurcated rectangular waveguide that couple to even and odd waveguide modes. One linear polarization is excited by the even or sum mode and the orthogonal linear polarization is excited by the odd or difference mode. By superposing the sum and difference modes in the proper amplitude and phase, any arbitrary polarization can be synthesized. A two-dimensional array consisting of eight waveguide linear arrays, farrite phase shifters for scanning in the plane normal to the linear arrays and a feed natwork for power distribution and polarization control was constructed. Good radiation performance for various polarizations was obtained. In the case of linear polarization, the cross polarization component was down on the order of minus 25 db and in the case of circular polarization, the exist ratio was on the order of 1 db. The polarization was controlled with a phase shifter. Close in sidelobes of better than 20 db were obtained for all polarizations. Author

N74-31708 Fernmeldetechnisches Zentralamt, Darmstadt (West

STEPPED REFLECTOR ANTENNA WITH A SECTOR SHAPED MAIN BEAM

H. Thielen In AGARD Antennas for Avionics 15 p refs (For availability see N74-31667-21-09)

The optimum pattern of an antenna of telecommunication or television broadcasting agailities consists in a sector shaped main beam without any side lobes. In this case the edge gain is 4.1 db higher than that of a conventional antenna. Theory Indicates that such a pattern is produced by a circular aperture illuminated by the oscillating function. Measurements were made with a paraboloid reflector untonna containing a dielectric dish in its central zone. This dish effects a phase reversal of 180 deg between the central zone and the remaining ring zone of the reflector, the edge gain of this untenne is 1 do higher than that of a conventional entonna. An Increase of 1.4 db obtained by a better feed system. It is also possible to achieve the phase reversal by an arrangement of metallic stens with a height of about one quarter wavelength. If an antenna with two or more ring zones is used, a further increase of the edge gain can be obtained

THE DESIGN OF MOS INTEGRATED CIRCUITS

R. A. Hilbourne In AGARD Custom Design for Large Scale Integration (LSI) Apr. 1975 20 p refs (For availability see N75-25047 16-33

The principles, constraints, and techniques which determine the methods used for the design of metal axide semiconductor integrated circuits are described. The two basic approaches are unichannel circuits, using either p or n channel transistors, and complementary circuits, using a combination of both types of translators. The technologies and circuit implications of these two approaches are discussed and related to the large scale integration requirements of high packing density and low power discipation per gate. The concepts of dynamic and static logic and the advantages of combining enhancement and depletion devices in a circuit are included. The design procedure is described and circuit subsystems and the complete circuit are simulated on a computer to ensure proper operation. The mask circuit layout is also simulated the check for correspondence with logic

CSCL 09C

The standard cell design automation technique is described as an approach for generating random logic PMOS, CMOS or CMOS/SOS custom large scale integration arrays with low initial inonrecurring costs and quick turnaround time or design cycle. The system is composed of predesigned circuit functions or cells and computer programs capable of automatic placement and interconnection of the cells in accordance with an input data net list. The program generates a set of instructions to drive an automatic precision artwork generator. A series of support design automation and simulation programs are described, including programs for verifying correctness of the logic on the arrays, performing dc and dynamic analysis of MOS devices, and generating test sequences.

AN INVESTIGATION OF DIFFERENT TECHNIQUES FOR UNSTEADY PRESSURE MEASUREMENTS IN COM-PRESSIBLE FLOW AND COMPARISON WITH LIFTING SURFACE THEONY

R. Destuynder (ONERA) and H. Tijdemen (NLR, Amsterdam, Netherlands) Jan 1974 35 p. Presented at the 37th AGARD Struct, and Mat. Panel Meeting, The Hague, 7-12 Oct. 1973 (AGARD-R-617) Avail NTIS HC \$475

Wind tunnal measurements of unsteady aerodynamic pressures at high subsonic speeds were conducted. The recults obtained by two different procedures are presented. Flutter tests were also conducted on the same model as that used for unsteady pressure measurements. Natural frequencies and damping values were determined at constant Mach number and varying free-stream dynamic pressure. Tables of data and graphs are included to compare the results obtained by the two nethods Author

THEORY OF FLOWS IN COMPRESSIBLE MEDIA WITH

HEAT ADDITION Juergen Zierep (Karlsruhe Univ.) May 1974-65 p. refs (AGARDograph-191; AGARD-AG-191) Avail: NTIS HC \$6.25

A systematic survey is undertaken of the theory of the effect of a given heat addition on the flow of a compressible medium. Here steady flows, both one-dimensional and multi-dimensional. linear and nonlinear, are treated. Consideration is given to addition of mass and momentum to a streamtube as well as of energy. interesting equivalences arise here. The heat can be distributed continuously in the flow field or added at fronts. For practical applications, the reduction of the drag of a body in flight by heat addition in the flow field is important. At extremely high velocities the problem arises of propulsion by external combustion. Here, the energy is to be transferred directly to the flowing medium, at the high velocity. For the evaluation of such an energy addition, reference is made to the propulsive efficiency. as well as the lift and dray of the body

AERODYNAMIC MEASUREMENTS IN CASCADES

M. C. Sieverding, H. Starken (DFVLR), H. J. Lichtfuss, and P. Schimining In AGARD Modern Methods of Testing Rotating Components of Turbomachines (Instrumentation) p 1-76 refs (For availability see N75-30471 21-34)

The usefulness of cascade flow measurements used to acquire detailed blade performance data is discussed. The design of a cascade wind tunnel is described. Factors considered include: two dimensional and periodic flow, variations of inlet and outlet conditions, and three dimensional effects. Data reduction methods are presented along with factors which influence the choice of appropriate pressure probes.

N75-30473 Air Force Aero Propulsion Lab., Wright-Patterson AFB. Ohio

AERODYNAMIC MEASUREMENTS IN TURBOMACHINES David W. Fleeger and Noel J. Seyb (Rolls-Royce, Ltd., Bristol, Engl) In AGARD Modern Methods of Testing Rotating Components of Turbomachines (Instrumentation) Apr p. 79-121 refs (For availability see N75-30471 21-34)

The problems encountered in designing instrumentation for component and engine testing are discussed. Trade-offs must be made between probe strength, blockage, accuracy, cost, and installation problems. Many of the basic parameters often measured are summarized in tabular form listing typical methods and citing references. Conventional techniques concerning pressure (steady state and high response) and gas temperature measure-ment are discussed in detail. Methods to couple the use of both steady state and high pressure transducers involve the flush mounted diaphram, resonant tube, resonant damped and non-resonant tube methods. Special considerations are required to measure the time weighted value of a high frequency pressing signal. For thermocouple design many factors including wire type, recovery, convection, conduction, radiation, chemical reactions, and time response are considered. Calibration techniques are discussed for both pressure probes and thermocouples. Typical probe designs with calibration data which were provided by engine manufacturers are compared.

UNSTEADY FLOW MEASUREMENTS IN TUR-BOMACHINERY

H. Wayer and R. Schodl. *In its* Modern Methods of Testing Rotating Components of Turbomachines (Instrumentation). Apr. 1975. p. 141-182. refs (For availability see N75-30471. 21-34).

Determination of strong pressure oscillations of high frequency and high amplitudes which occur in the region of turbomachine rotors is considered in terms of immediate measuring of the fluctuating pressures at the casing in the rotor zone, as well as behind the rotor exit plane, and determination of the average pressures resulting from these oscillating pressures. The application of the modern high response pressure transducers and of new techniques, which enable the measurement of well defined average values of the oscillating pressures in turbomachines are described along with a method for instantaneous flow angle measurement in centrifugal compressors. Emphasis is placed on the development of a laser dual beam technique for flow volucity measurements in turbomachines.

NUMERICAL TECHNIQUES FOR THE SOLUTION OF THE COMPRESSIBLE NAVIER-STOKES EQUATIONS AND IMPLEMENTATION OF TURBULENCE MODELS

Barrett S. Baldwin, Robert W. MacCorrnack, and George S. Deiwert In AGARD Computational Methods for Inviscid and Viscous Two-and-Three-Dimensional Flow Fields Feb. 1975 24 p. refs. (For availability see N75-31385 22-34)

The time-splitting explicit numerical method of MacCormack is applied to separated turbulent boundary layer flow problems Modifications of this basic method are developed to counter difficulties associated with complicated geometry and severe numerical resolution requirements of turbulence model equations. The accuracy of solutions is investigated by comparison with exact solutions for sevaral simple cases. Procedures are divisitional solutions of high-Reynolds-number separated flows over an airfoil and shock-separated flows over a flat plate are obtained. A simple mixing length model of turbulence is used for the transonic flow past an airfoil. A nonorthogonal mesh of arbitrary configuration facilitates the description of the flow field. For the simpler geometry associated with the flat plate, a rectangular mesh is used, and solutions are obtained based on a two-equation differential model of turbulence.

51 p. refe. Sponsored by ERDA (For availability see N75-31385
22-34)

The status of the numerical computation of boundary layers is given for two- and three-dimensional flows. The appropriate transformations to apply to the governing equations are considered, and the possible solution procedures are dismissed. Emphasis is on the finite-difference procedures which are illustrated for two-dimensional, incompressible flows. For compressible flows the Crank-Nicolson technique is given. The changes which are needed to this approach when the flow is turbulent, are presented. The finite-difference procedures utilized for unsteady flows are given. Solution techniques for three-dimensional flows are described and the features which are different from two-dimensional flows are emphasized.

L. R. Harper In AGARD Improved Nozzle Testing Tech. in

Transonic Flow Oct. 1975 22 p refs (For sveilability see N76-16357 07-34)

Three nozzle afterbody models were tested in the Rolls-Royce (1971) Ltd. transonic wind tunnel at Bristol using a model support sting which provided means for boundary layer thickness variation by blowing. The tests covered the Mach number range 0.75 to 0.95 and nozzle pressure ratios were in the range 1.7 to 4.7:1, The model surface static pressure distributions were meanured and integrated to obtain pressure drag coefficients. Measurements are also presented of model internal pressures, boundary tayer profiles and tunnel wall static pressure distributions.

N76-16360 Deutsche Forschungs- und Versuchsanstelt füer Luft- und Raumfahrt, Brunswick (West Germany) AN EXPERIMENTAL STUDY OF THE INFLUENCE OF THE JET PARAMETERS ON THE AFTERBODY DRAG OF A JET ENGINE NACELLE SCALE MODEL

H. Dissen and A. Zacherles In AGARD Improved Nozzle Teating Tech. in Transonic Flow Oct. 1975 14 p ref (For availability see N76-16357 Q7-34)

Numerous experimental tests with an engine nacelle scale model were made to investigate the influence of engine jet parameters on the pressure distribution of the engine nacelle and therefore on the boattail pressure drag. Regarding the planned flight tests on the HFB 320 Hansa Jet at the end of 1975, the experimental work was done with a model of the GE CJ 610 angine nozzle, including its nacelle. The influence of jet pressure ratio and jet temperature on the boattell pressure distribution at different flight Mach numbers are shown. The effect of boundary layer control and the influence of changing the internal nozzle geometry on the pressure dreg is also investigated.

H. Emunds and H. Riedel In AGARD Improved Nozzle Testing Tech. In Transcrite Flow Oct. 1975 42 p (For availability see

N76-16357 07-34)

The results presented relate to the AGARD models with 10 day and 15 day boattall chord angle. They cover the static pressure distributions on the afterbody and wall of the propulsive nozzle as well as the total pressure distributions in the nozzle flow and in the external flow field. The latter was only investigated for the model with 10 deg boatteil. From the surface stallo pressure distributions on the afterbody of the models the boattail pressure dray coefficient was deduced. A cold propulsive jet of air was used, the nozzle total pressure ratio ranging from 1.0 to 6.63. The free stream Mach numbers covered the regime 0.5 free stream Mach number < 0.96.

N75-16362 National Aerospace Lab., Amsterdam (Netherlands), RESULTS OF NLR CONTRIBUTION TO AGARD AD HOC BTUDY

D. Rozendal, C. C. Groothoff, and W. B. G. Derkeen. In AGARD Improved Nozzle Testing Tech. in Transonic Flow Oct. 1975 41 p refs (For availability see N76-16357 07-34)

A description is given of a series of experiments in order to assess the influence of jet exhaust parameters - total pressure distortion, nozzle pressure ratio, let temperature (ratio of specific heats) - at transonic Mach numbers in the range of .8 to .96 on the nozzle thrust and discharge coefficients, on afterbody pressure distribution, and un the afterbody pressure drag. A model of .08 m diameter was tested in the .27 x .27 sq m transonic test section of a continuous blow-down wind tunnel. The 15 deg boattailed afterbody configuration as proposed by AGARD was supplemented by an afterbody with a twice as large nozzle area The fuseinge boundary layer thickness was varied by increasing the forebody length. A method was developed to define a valid total pressure, based on a mass flow averaging procedure, for a distorted jet pips flow. The results for the AGARD nozzle, contraction ratio 3.24, show that in the investigated range of NPR's there is only a small effect due to the jet pipe total pressure distortion, while for the larger nozzle with a contraction ratio of 1.82 the hollow velocity profile, compared to a flat profile, significantly lowered the nozzle discharge coefficient (3.2%), raised the specific thrust + 2.1% and changed the afterbody pressure distribution at free stream Mach number - .8. Effects on afterbody pressure distribution and pressure drag due to different NPR and free stream Mach number were evident, while an influence due to fuselage boundary layer thickness is

EFFECTS OF VARYING REYNOLDS NUMBER AND BOUND-ANY LAYER DISPLACEMENT THICKNESS ON THE EXTERNAL FLOW OVER NOZZLE BOATTAILS

D Zonais, James A. Laughrey, and Douglas L. Rowers. In AGARD Improved Nozzie Testing Tech. in Transonic Flow Oct. 1975

28 p. refs (For availability see N76-16357 07-34) .
Data for the 10 deg. 15 deg. and 25 deg AGARD nozale boattails presented are from those test facilities in which the Reynolds number was varied at constant Mach number or where the boundary layer was varied by blowing or changing the length of the model. Evaluation and discussion of the data concentrates on the trends in pressure drag and static pressure distributions when the external flow conditions (specifically Reynolds number and/or boundary layer displacement thickness) are altered over the Mach number range of 0.8 through 0.95. In general when the Reynolds number was increased or the boundary layer displacement thickness was decreased, the static pressures decreased at the beginning of the boattall (flow expansion region) and increased near the nozzle exit (flow recompression region). The pressure drags associated with these changes in the pressure distributions varied only slightly at 0.8 Mach number, but increased measurably at 0.9 Mach number. Increasing the Reynolds number or decreasing the displacement thickness at a Mach number of 0.95 changed the flow such that the expansion was greater and the recompression was less resulting in a significant increase in pressure drag. The flow separated just downstream of the shoulder on the 25 deg boattail for all Mach numbers investigated and a change in Reynolds number or displacement thickness did not noticeably influence the point at which the flow separated although there was some variation on the level of pressure in the separated zone. Air Force Station, Tenn.
DESCRIPTION OF THE AGARD NOZZLE AFTERBODY
EXPERIMENTS CONDUCTED BY THE ARNOLD ENGINEER-ING DEVELOPMENT CENTER

L. L. Gullgher, F. M. Jackson, and C. E. Robinson In AGARD Improved Nozzle Testing Tech. in Transonic Flow Oct. 1975 6 p. refs (For availability see N76-18357-07-34)

A comprehensive test program, directed toward evaluation of Reynolds number and exhaust plume temperature effects on nozzie alterbody pressure drag, was conducted. Reynolds number effects were obtained by varying both model scale and wind tunnal pressure level. At AEDC, Ethylene(R)/air combustor, matalled in the nozzle flow tube, was used to provide hot exhaust products which very closely duplicate the exhaust products of JP-4 burned in air. Ignition was accomplished by injecting a small quantity of tri-ethy) borane (a pyrophoric fuel) into the combustor flameholder. Nozzle afterbody pressure drag, determined from pressure integration, was obtained at freestream Mach numbers of 0.6, 0.8, 0.9, 0.95, 1.1, and 1.5. Reynolds number (based on mode) length) and nozzle total pressure-to-free-atream static pressure ratio was varied from 2 million to 62 million and from jet-off to a maximum of 22, respectively, depending upon the free-stream Mach number. Fuel/air ratio was varied from 0 to 0.05, which corresponds to an exhaust plume total temperature range from 308 K to approximately 1889 K. Model angle of attack was zero degrees at all test conditions. To evaluate the affect of test section wall porosity on the performance of transonic wind tunnels the walls were modified for wall porosities of 2 and 4 percent in addition to the normal 6 percent, through the Mach number range from 0.6 to 0.95. CONTRIBUTION OF THE NATIONAL AERONAUTICS AND SPACE ADMINISTRATION LANGLEY RESEARCH CENTER William B. Compton, III and Jack F. Runckel. In AGARD Improved Nozzle Testing Tech. in Transcnic Flow Oct. 1975 9 p refs (For availability see N76-16357 07-34)

As part of a special international effort, three nozzlos were designed and tested on single nacelle models in wind tunnels of several nations belonging to the North Atlantic Treaty Organization. All three of these nozzles were investigated in the Langley 16-foot transonic wind tunnel at the National Aeronautics and Space Administration's Langley Research Center, Langley Research Conter also contributed theoretical calculations of the jet plume boundary and afterbody pressures. The calculations were obtained using an iterative solution which combined the invisoid Douglas Neumann method for the external flow with the method of characteristics for the flow in the jet plume. For the investigation, the nottles were mounted on a single nacelle model 15.24 centimeters in diameter and 162.58 centimeters long. Tests were made at free stream Mach number from 0.4 to 1.2, and at Reynolds numbers per meter from 7.38 million to 13.78 million depending on the Mach number. Four types of data were recorded: afterbody pressure data, afterbody force data, model boundary layer data, and tunnel well pressure data. The ratio of jot total pressure to free atream static pressure ranged up to 8.5. A description of the wind tunnel, model, and test procedure is included.

N76-16366 Rolls-Royce, Ltd., Bristol (England). THE INFLUENCE OF MODEL EXTERNAL GEOMETRY L. R. Harper and W. J. Lewis In AGARD Improved Nozzle Testing Tech. In Transonic Flow Oct. 1975 11 p refs (For availability see N76-16357 07-34)

The results of model tests of three axisymmetric afterbodies in a number of different wind tunnels were examined in terms of the influence of model external geometry. The variation of drag with afterbody geometry was shown to be in accord with the trend for drag to increase and drag rise Mach number to decrease as the body is made less siencier. It is found that drag and drag rise Math number can be correlated quite well with boattall chord angle for a wide range of afterbody geometries in addition to those tested in this exercise. Increase of boundary layer thickness was shown to decrease the affective curvature of the afterbody. At speeds below the drag rice Mach number for any particular geometry this modifies the afterbody pressure distribution but has little effect on the pressure drag. Above the drag rise Mach number drag coefficients measured with a boundary layer thickness typical of model test conditions were about 0.01 lower than when the boundary layer thickness was reduced to a value typical of flight conditions. Comparison of results obtained in various wind tunnels covering blockage ratios from 0.2% to 7% failed to show any discernable effect of tunnel interference at least for Mach numbers up to about 0.9 to 0.95. At high blockages static pressure varies considerably along the tunnel wall and it becomes crucial to select a reference static pressure which is substantially free from the influence of the afterbody pressure field. The overall conclusion is that results obtained in the various facilities are in good agreement and the techniques of afterbody drag measurement in current use are generally satisfactory although correct simulation of boundary layer thickness is sometimes necessary. INFLUENCE OF THE JET PRESSURE RATIO ON THE
PERFORMANCE OF AN AGARD SINGLE FLOW AFTER-BODY IN THE 0.50-0.38 MACH RANGE

Bernard Mechin and Jean-Marie Hardy In AGARD Improved Nozzle Testing Tech. in Transonic Flow Oct. 1975 8 p. refs in FRENCH; ENGLISH summary (For availability see N76-16357 07-34)

The synthesis of experimental data concerning the effect of jet stagnation conditions on the drag of various afterbodies is presented. Jet pressure ratio effect on boattail pressure and on boundary layer separation is analyzed. This study is made for several values of the boundary layer thickness, taking into account the fact that some test rigs make its control possible by means of tangential blowing.

C. C. Groothoff In AGARD Improved Nozzle Testing Tech, in Transonic Flow Oct. 1975 22 p refs (For availability see N76-16357 07-341

internal flow and nozzle characteristics were analyzed. All available data were used in a comparison of the nozzle discharge and thrust coefficients and jet pipe wall static pressures of similar model configurations. It was found necessary to take into account the distortion of the total pressure profiles in the jet pipe. The mass flow averaged total pressure was used in the calculations. The distortion coefficient DCM proved to be a useful tool in the comparison of the mass flow averaged total pressure with the 1-D isentropical total pressure, derived from mass flow, temperature and static pressure. The discharge coefficients that were found in the range of nozzle pressure ratios of about 1.3 to 12 were in good agreement. For the specified nozzle A the discharge coefficient Cd = 986. For this nozzle configuration with a contraction ratio of 3.24 hardly any influence on Cd of jet medium or distortion was found. External air flow did influence Cd. monly through the boattail overpressure near the nozzle lip. The thrust coefficients were found to be difficult to compare, one set of data however shows an inexplained higher level (about 1 - 2%). Nozzle 8 (contraction ratio 1 62) showed more influence of distortion in the jet flow. The values for the choked nozzle discharge coefficients were Cd = .978 (no dist.) and Cd = 946 (dist.). Distortion was also found to influence the well static pressures in the jet pipe.

INFLUENCE OF JET FARAMETERS: BOATTAIL PRESSURE DISTRIBUTION AND PRESSURE DRAG.
H. Dissen, H. Emunds, H. Riedel, and A. Zacharlas // AGARD Improved Nozzle Testing Tech, in Transonic Flow Oct. 1975

17 p. refs (For availability see N76-16357 07-34)
Preliminary results are presented of the influence of the jet parameters on the boattail pressure distribution and on the boattail pressure drag with reference to the AGARD models and a model of the HFB 320 engine nacelle. The jet parameters investigated were the jet temperature, the wake and jet mixing, the internal nozzle configuration, and the jet distortion. Concerning the influence of jet temperature two contrasting effects were observed. These differences may be due to different surface temperatures and base areas of the models tested. Further investigations are regards these temperature effects seem to be necessary. Very little information has become svailable on wake and jet mixing, so that in this area further research is also needed. No effect was observed for changes of the internal nozzle geometry and of the jet distortion.

DATA VARIANCE DUE TO DIFFERENT TESTING TECH-

NIQUES

J. A. Laughrey, G. K. Richey, and Antonio Ferri, (N. Y. Univ., N. Y.) In AGARD Improved Nozzle Testing Tech. In Transonic Flow Oct. 1975 21 p. rets (For availability see N70-16357 07-34)

A comparison of the boattail pressure distributions from data presented earlier shows that there is a significant variance in the data obtained in the various facilities, particularly at 0.9 and 0.95 Mach numbers. The analysis is concentrated on the 15 deg AGARD hoattall tested in the 0.8 to 0.95 Mach number range Differences in model support, model scale, tunnel blockage, tunnel buoyancy, wall type and poresity, and determination of tunnel reference flow conditions are examined in an attempt to understand the disagreement in the data. Model and wall static pressure distributions from various facilities are analyzed to try to isolate the reasons for these differences and to determine if there is a significant effect on the flow over the nozzle boattail. An Indication of possible wall interference is obtained by comparing the measured wall static pressure distributions to those determined analytically with a far field boundary condition corresponding to free flight conditions.

FORE- AND AFTSODY FLOW FIELD INTERACTION WITH CONSIDERATION OF REYNOLUS NUMBER EFFECTS
Felix Aulenta and Geart Besigk In AGARD Improved Nozzle

Testing Yech. in Transonio Flow Oct. 1975 22 p refs (For

svallability see N76-16357 07-34)

Recent affbody drag results obtained from different transonic wind tunnel measurements showed such large increases in affbody pressure drag with increasing Reynolds number that extrapolation to full soals became questionable. Attempts made to clarify this unexpected Reynolds number effect with the aim of contributing to improved testing techniques are outlined An analysis of a wind tunnel investigation at Mach number C,8 on a series of axisymmetric bodies showed as main result that varying Reynolds number produced in the wind tunnel opposite changes in pressure drag on fore- and affbody, respectively. It is explained that this result probably was caused by small deviations in free stream static pressure to which part-models are by an order of magnitude more sensitive than complete models. Therefore, unless a wind tunnel is celibrated to considerably better standards than usual it is recommended to take into account the compensating effects

on the forebody; the buoyancy corrections due to pressure gradients, however, have to be considered in addition. In the present measurements the changes of the mean wall pressures seemed to correlate with the corresponding changes on the model and were used as a correction term. Finally it is pointed out that modifications in aftbody geometry affect forebody drag. Results from the commonly used aftbody test rigs with forebodies fixed to the ground therefore need appropriate corrections.

FLUIDICS TECHNOLOGY

J. M. Kirshner, ed. (Harry Diamond Labs., Adelphi, Md.) Jen. 1976 592 p. refs

(AGARD-AG-215; AGARDograph-215) Avail: NTIS

This AGARDograph is based on material presented at a symposium on fluidies held by the Harry Diamond Laboratories of the United States Army. It largely represents a selection of material from the proceedings of this symposium, edited in the interests of a wider audience. The compilation is an overview in concise form of the present state of research, technology and applications of fluidics. An opening seution on sensors is followed by sections on circuit components, systems and signal sepects, and design and application. A final section is concerned with research and febrication needs in the future. The table of contents of the original HDL Symposium is appended. For individual titles, see N78-21431 through N76-21448.

ANALYTIC DESIGN OF LAMINAR PROPORTIONAL
AMPLIFIERS

Francis M. Menion and Tadausz M. Drzewiecki *In* AGARD Fluidios Technol. Jan. 1976 p 157-207 refs (For availability see N76-21430 12-34)

The analytic design of laminar proportional amplifiers is discussed. After a historical review of analog fluidic devices, the advantages of and rationale for using laminar devices are shown. Among some of the more desirable features of laminar devices are the improvements obtained in gain, dynamic range and signal-to-noise ratio, not to mention the ease of scaling. A general geometric configuration for laminar proportional (analog) amplifiers is presented that considers control and output-port width, splitter-to-nozale distance, splitter thickness, aspect ratio, and spacing between downstream edges of the control portanormalized to the supply nozale width as the parameters of

1

concern in design. The approach geometry, such as the supply, control, output and vent lines, is treated in terms of known viscous impedance variables. Staging techniques are presented

N78-21440 Lehigh Univ., Bethlehem, Pe. ANALOG FLUIDIC CIRCUITRY: REVIEW, CRITIQUE AND A NEW OPERATIONAL AMPLIFIER Forbes T. Brown In AGARD Fluidics Technol.

p 389-407 refs (For availability see N78-21430 12-34)
Two different approaches to analog fluidic circuitry are found in the literature. The first utilizes high gain amplifiers with feedback (operational amplifiers) to achieve easy design, excellent linearity, low noise and low sensitivity to disturbances at a cost of limited bandwidth, high power consumption and high expense. The second utilizes fewer emplifiers with feed-forward and a minimum of feedback to achieve the opposite consequences. An operational amplifier is proposed which, through resonance tubes placed in

the forward loop upstream of the gain block, has a greatly extended bandwidth at a cost of increased sensitivity to load changes at high frequencies.

N76-21441 Harry Diamond Labs., Adelphi, Md. FLUIDIC NOTCH FILTERS

Gary L. Roffman In AGARD Fluid Technol. p 409-443 refs (For availability see N75-21430 12-34)

Ten notch-filter circuits with biquadratic transfer functions are described. Notch filters are used in control systems to prevent instabilities due to mechanical resonances. The electronic circuit literature was searched to find circuits with biquadratic transfer functions that could be implemented with fluidic amplifiers. The amplifiers are assumed to have equal input and output impedances, and all high-gain emplifiers used are assumed to have a pressure gain of 2,000. Using these characteristics, the frequency response of the circuits is calculated using a digital, discult-enalysis program. The best circuit, based on accuracy in producing a required transfer function for the MBOA1 tank control system, gain insensitivity, and least number of compliances (bellows) requires three high-gain amplifiers. Advantages and disativantages of all the circuits are

N76-21442 Harry Diamond Labe., Adelphi, Md. CIRCUIT MODELS OF PASSIVE PNEUMATIC FLUIDIC COMPENSATION NETWORKS

Joseph M. Iseman In AGARD Fluidic Technol. p 445-484 refs (For availability see N76-21430 12-34)

Circuit models of passive pneumatic fluidic components are summarized, and the feasibility of a circuit approach for designing passive fluidic control system circuits is described. Starting with a set of fluidic components: capillaries, enclosed volumes, believes modules, and diaphragm modules. Circuit models were synthesized from an analytical-experimental-computational approach. Simple, kiest electronic circuit models that are linear and frequency independent were extended to models that are nonlinear and frequency dependent. These circuit models are described by analytic expressions. A few test configurations were built and their responses were measured. Simulation for these configurations was performed with digital computer programs. Comparisons between the test data and simulated models were made and qualitatively evaluated; these data are generally in agreement over the ranges tested.

N76-21443 Harry Diamond Labs., Adelphi, Md. FLUIDIC STANDARDIZATION EFFORTS

R. Pierce Tresk, II In AGARD Fluidics Technol. Jan. 1976 p 487-496 (For evallability see N76-21430 12-34)

Fluidic standards are discussed with respect to their development, subject material, use within the fluidic technology, and to some extent their relationship to other technologies. The many groups that are active in developing standards and the standard documents they issue are described. Among the most active groups are the Government Fluidics Coordination Group (GFCG) and the National Fluid Power Association (NFPA). Two military standards on fluidic terminology, symbology, and test mathods, were developed and recently revised by the GFCG. Two additional standards on moving-part fluid-logic symbols and data presentation were developed by the NFPA. These four documents form the framework of the current fluidic standards used in the United States. Author

The calculation is discussed of laminar separation which has always represented one of the most relevant problems of boundary layer theory, even within the classical Prendtl's assumption of vanishing transverse pressure gradients. Recent theories attempting to calculate separation after relaxing Prundit's assumption are reviewed. Purely numerical results based on the finite difference solution of the complete Navier-Stokes equations are harely mentioned. The analytical procedure based on a multiple layer treatment developed independently by Neiland and by Stewartson and Williams is discussed in detail both in the foundations and in the developments. Some as yet unmentioned results are also given. A critical discussion follows, showing the insufficiency of the present asymptotic treatment of the return flow. A third procedure is thought to present a certain interest, that is the generalization of von Karman momentum Integral procedure taking into account the existence of transverse pressure gradients. The attempt by Holden and Moselle, containing some arbitrariness. is montioned it is shown how the arbitrary elements can be removed and a perfactly coherent set of equations in integral form obtained. The possibility is shown of a fundamental improvement in the calculation of the distributions through the use of a three or four-parameter family of generalized similar solutions taking into account the transverse variability of the

This survey deals with flows of a gas in which small, rigid, and permanent particles are suspended. Particle concentrations range from so low that the particles do not affect the gas flow and can be treated as single particles to so high that the particles occupy an appreciable volume fraction of the mixture. The dynamics of single particles in continuum and low-density flow, the themodynamics of gas-particle mixtures, and the basic flow equations for one-dimensional flow are discussed. Wave propagation, nozzio flow and gas-particle jets are also discussed Additional examples of analytical and experimental results are given to illustrate important ultuations. Emphasis is placed on work performed in the United States.

TESTING OF PRECISION INERTIAL GYROSCOPES

Dino A. Lorenzini (Air Force Acad.) Jun. 1974-73 p. refs (AGARD-AG-192; AGARDograph-192) Avail. NTIS HC \$6.75 The basic phases of environment, excitation, monitor, and evaluation involved in inertial sensor tests are reviewed Techniques considered for application to known gyro testing problems are described, and base motion environment, computercontrolled test operation, data acquisition, and data handling problems are identified. The studies suggest that the development of a more comprehensive gyro error model is needed to uncover some of the coefficient disagreements and instabilities which occur between different tests, and different test equipment. Mini-computers are discussed in terms of their advanced capabilities in data acquisition and processing methods for improved test accuracy speed, and versatility.

EVALUATION OF THE POTENTIAL BENEFIT TO THE AERONAUTICAL FIELD FROM LASER TECHNOLOGY Dec. 1974 251 p refs Parly in ENGLISH; party in FRENCH (AGARD-AG-195; AGARDograph-195) Avail: NTIS HC \$8.50

The characteristic properties of lasers are reported and their applications to aeronautical engineering are discussed. For individual titles, see N75-16829 through N75-16843.

N75-16829 Royal Radar Establishment, Maivern (England). REVIEW OF CHARACTERISTIC LASER PROPERTIES M. J. Taylor In AGARD Evaluation of the Potential Benefit to the Aeron. Field from Laser Technol. Dec. 1974 24 p. refs (For availability see N75-16828 08-36)

Lisers can be made from solid, gaseous or liquid materials, and the emission may be either continuous wave (CW) or pulsed, depending on the system. The range of CW power in laser beams varies from milliwatts to kilowatts and pulsed systems give peak powers of up to terrawatts with pulse widths in the picosecond range. The energy in such short, intense pulses may not, however, be very high. The principles and properties of lasers are summarized, emphasizing aspects which are particularly relevant to avionic systems design.

AIRBORNE INSTRUMENTATION ALTIMETERS, DOPPLER-NAVIGATORS, VELOCIMETER, CAT-DETECTION

F. Malota In AGARD Evaluation of the Potential Benefit to the Aeron. Field from Laser Technol. Dec. 1974 12 p refs (For availability see N75-16828 08-36)

The possible uses of lasers in airplanes as altimeters, velocimeters, for Doppler navigation and for clear air turbulence detection are discussed. It is shown that the shorter wavelengths of lasers have some advantages over microwaves and radiowaves in avionics applications.

N78-16833 Army Electronics Command, Fort Monmouth, N.J. THE APPLICATION OF LASERS TO THE PROBLEMS OF VERY LOW LEVEL FLIGHT OBSTACLE AVOIDANCE AND TERRAIN FOLLOWING

C. M. Kellington In AGARD Evaluation of the Potential Benefit to the Aeron. Field from Laser Technol. Dec. 1974 9 p. refs (For availability see N75-16828 08-36)

Lasers have found application in helping to solve the problems of very low level flight by U.S. Army aircraft. In the following is discussed: the reasons why Army aircraft fly low, the nature of the operational problems encountered at low altitudes, the technical problems associated with the design of systems to enhance low level flight capability, research efforts to date directed toward solution of the problem of low level flight and finally a comparison of the capabilities of microwave and laser systems in this area. The limitations of laser systems and research areas still requiring investigation are also discussed.

R. H. Kingston In AGARD Evaluation of the Potential Benefit to the Aeron. Field from Laser Technol. Dec. 1974 3 p. Sponsored by Dept. of the Air Force (For availability see N75-16828 03-36)

The use of a laser for illumination offers many advantages over reconnaissance and surveillance using either standard photography or microwave rader. Foremost among these advantages are high resolution images not dependent upon daylight, much higher resolution than that obtainable with rader, and the possibility of range-gating for suppression of foreground backscatter as well as range determination. In this review of the use of lasers in sirborne surveillance and reconnaissance, the detailed advantages of such systems, the types of systems and possible applications, and the problem areas requiring further research and development are discussed.

J. A. Boden In AGARD Evaluation of the Potential Benefit to the Aeron. Field from Laser Tsr:hnol. Dec. 1974 20 p. refs (For availability see N75-16828 08-36)

A survey is given of the most common types of coherent optical correlators, which are classified as spatial plane correlators. frequency plane correlators and special reference correlators. Only the spatial plane correlators are dealt with rather thoroughly. Basic principles, some special features, advantages and disadvantages mostly are given with references to relevant literature. Optical processing of sideways looking synthetic aperture radar data and the acousto-optical processing of linear FM radar signals are described as special reference correlators, of which the first has become the most important application of optical data processing to date. Some advantages and disadvantages of incoherent correlators are given for comparison along with some examples of the most common types. A detailed description of a simple coherent anatial plane correlator is given. Some experimental results are mentioned. The reference function in this correlator is realized as a hard clipped phase plate, which susuits in a large detection region and a high signal output.

ATMOSPHERIC LASER BEAM PROPAGATION

A. Laurens. In AGARD Evaluation of the Potential Benefit to the Aeron, Field from Laser Technol. Dec. 1974 21 p. refs in FRENCH; ENGLISH summary (For availability see N75-16828 08-36)

Laser beam propagation is modified by absorption, by scattering and by turbulence. Absorption in the atmosphere is brought about by molecular constituents. The absorption by scattering depends on Rayleigh scattering and Mie scattering: Rayleigh scattering can be neglected for wavelengths longer than 0,5 microns. Mis scattering is related to the dimensions of the particles; the attenuation of hazes and selective fogs decreases when the wavelength increases. The effects of turbulence on laser beam propagation are beam apreading, beam deviation. amplitude and phase variations whose consequences are scintillation and coherence losses; those effects are more important for short wavelengths than for long wavelengths.

ADVANCED MANUFACTURING METHODS AND THEIR ECONOMIC IMPLICATIONS: SOME PILOT PAPERS ON POWDER METALLURGY AND JOINING

Mar 1975 112 p refs in ENGLISH, parily in FRENCH (AGARD-R-627) Avail NTIS HC \$5.25

A systematic eximination of the field of advanced fabrication techniques is reported, together with an analysis of the impact of these new procedures on costs. Six papers, given before the AGARD Structures and Materials Panel in the spring and fall of 1974, are contained in this document. These six papers explore the latest state-of-the-art and the potentials for future development of various methods of fabrication of serospace hardware. Analyzed in these papers are such areas as metal joining mathods, production techniques for dispersion-strengthened materials and various aspects of powder metallurgy. The six papers contained in this report constitute a pilot effort by the Structures and Materials Panel to determine the direction of future work of the panel in this important field. For individual titles, see N75-22750 through N75-22755.

PROCESSING OF DISPERSION HARDENED MATERIALS
G. Wirth In AGARD Advan. Manuf. Methods and their Econ.
Implications Mar. 1975 16 p. refs (For availability see N75-22749
14-27).

Production methods for dispersion-strengthened metals and alloys, especially materials for high-temperature applications, are reviewed including commercial as well as advanced experimental techniques. Their effect on mechanical properties and economic aspects are discussed. Because of the nearly exclusive application of powder-metallurgical techniques to the production of dispersionstrengthened materials, this production method preferably is discussed Also, special strengthoning mechanisms are pointed out. Compalisons are made to other high-temperature strengthening approaches as directional solidification of autentic alloys Advanced processes like ZAP, applied to mechanically alloyed dispersion strengthened age-hardenable superalloys, cancel the complicated and expensive thermomechanical treatments and seem to shift the dispersion strengthening up to a level of strength and economy comparable to the directional solidification of eutectics

Gammagraphy a nondestructive inspection technique derived from X-ray radiography utilizing a compact acure of radioactive material is examined in relation to application in alroraft maintenance. Topics discussed include: gamma-ray properties, sources, and energy; activity of a gamma-ray source; source activity decay, radiation quantity; specific radiation intensity; gamma-ray absorption, and compton scattering. Gammagraphy bhotography is described in detail along with equipment and safety rules. Applications in civil aviation are given.

38 QUALITY ASSURANCE AND RELIABILITY

The use of acoustic emission as a nonrestructive inspection technique is discussed. Each stage of the failure process is detected in real time starting with deformation, crack propagation, and the onset of instability. Areas of application discussed include low cycle high-stress-intensity fatigue, stress corrosion cracking and hydrogen embrittlement; strain-aging embrittlement; delayed well disacking, and continuous in-service surveillance. Limitations of acoustic emission techniques are summarized.

F. Rotvel In AGARD Non-Destructive Inspection Practices Oct. 1975 p 473-508 refs (For availability see N76-16477 07-38)

The effect of mean stress on fatigue strength and stress corrosion is discussed briefly. Processes by which residual stresses are created were studied; these include plastic deformation in regions with stress gradients, temperature gradients, chemical expansion or contraction surface material, and electroplating X-ray stress measurement using the film method of the diffractometer method was investigated, and comparisons were made between the two methods. The ultrasonic stress measuring method and the Knoop hardness stress measuring mothod are considered.

AVIONICS DESIGN FOR RELIABILITY

Mar. 1976 163 p. refs. (AGARD-LS-81) Avail. NTIS HC \$6.75

Problems of avionius reliability were discussed. Typical methods for forcing reliability into new design and development and into new procurement requirements were described including a discussion of the reliability between life cycle costs as affected by the reliability achieved. The case for improving initial designs with more background experience, greater patience and thoroughness by the designer is viewed as perhaps the soundest and in the long run the most economical mushs for reliability attemment. Case histories involving both reliability testing and field reliability achievement are described. For individual titles, see N76-24603 through N76-24614.

AVIONICS RELIABILITY CONTROL DURING DEVELOP-MENT

George T. Bird and G. Ronald Herd In AGARD Avionics Design for Reliability Mar. 1976 11 p refs (For availability see N78-24602 15-38)

A comparison was made between actual reliability growth observed during recent years and the inherent reliability potential for avionics equipment. A method of control is presented integrating prediction procedures currently outlined in MIL-STD-756 and MIL-HDBK-217 with development testing. A nomegraph is presented for determining the amount of design support testing which will be required to achieve a desired or specified value of avionics equipment reliability. It is shown how these control procedures are used for specification, design planning, testing, and monitoring high reliability achievement in avionics equipment.

N76-24604 Royal Radar Establishment, Malvern (England). RELIABILITY GROWTH MODELLING FOR AVIONICS J. E. Green In AGARD Avionics Design for Reliability Mur. 1976 12 p. rafs (For availability see N76-24002 15-38)

The factors which influence the reliability of avionics were reviewed, with emphasis on the development phase. A method for providing progressive estimates of reliability achievement during the development phase was presented. Reference is made to the use of computer programs for these purposes, and for estimating costs. The validity of the Duane Model is considered against practical experience gained during development of military avionics. Explanations are given for observed deviations in the short and long term periods, and the need to make adjustments

for different environmental stress conditions is noted. Further verification of a mathematical law for the rate of appearance of types of systematic (pattern) failure is reported. A review of potential evicinic reliability was also given in relation to the increased use of microelectronics and the eventual limiting factors were considered.

Author

N76-24605 Sumerlin (W. T.), Hazelwood, Mo ILLUSORY RELIABILITY GROWTH

W. T. Sumerlin In AGARD Avionics Design for Reliability Mar. 1976 4 p. refs (For availability see N76-24802 15-38)

The present meaning of reliability growth was identified and contrasted to earlier concepts. Present needs to devise effective means for administuring the later phase of svionic development were recognized. It is during this development phase that an abundance of system failures caused by shortcomings of design, workmanship, and parts selection, mark more or less completely the inherent reliability achievable upon development completion. The mathematical uncertainty of prognosticating a valid schedule for elimination of all pattern failures and achievement of required reliability on the basis of early test experience is examined. It is concluded that accepted means must be used for quantitative MTBF measurement in the absence of pattern failures, and that quantitative values for MTBF produced by typical growth monitoring in 1.1 presence of an abundance of pattern failures can be dargarously misleading.

EXPERIENCED IN-FLIGHT AVIONICS MALFUNCTIONS

George T. Bird and G. Ronald Herd *In* AGARD. Avionics Design for Reliability. Mer. 1976, 10 p (For availability see N75-24602 15-38)

The status of current avionics reliability in the field has been evaluated by a study of 98 types of avionics equipment used in a variety of aircraft during a six-month period in 1970. The MTBFs were analyzed by aircraft type and by equipment category (i.e., communication, radar, flight controls, computers, etc.) to reveal correlations with functional complexity. About 4,000 in-flight malfunctions from one type of aircraft covering 28 different equipment types were investigated to show failure modes, repair actions, and probable design causes.

FAILURES AFFECTING RELIABILITY OF AVIONIC SYSTEMS

J. A. Gamler In AGARD Avionics Design for Reliability Mar. 1976 11 p in FRENCH and ENGLISH (For availability see N76-24602 15-38)

Att automatic system of technical information set up within the French Air Force in conjunction with a basic document, the technical action form, was described, and the principle and conditions of application of guaranteed reliability clauses were discussed. The objective of this system is to determine the actual reliability of a system under operational conditions and to detect the failures affecting reliability. This is not only indispensable in improving the reliability of the equipment considered, but also provides information that is essential in developing new generations of equipment. The main results obtained through this system regarding the actual reliability of equipment and the analysis of the failures affecting seliability were also reviewed.

IMPACT OF RELIABILITY IMPROVEMENT WARRANTY (RIW) ON AVIONIC RELIABILITY

C. A. Hardy In AGARD Avionics Design for Reliability Mar. 1976 12 p. refs (For availability see N76-24602 15-38)

Incentives provided by the Air Force to contractors of new systems to design and produce electronic equipment with low failure rates and low repair costs in operational use were described. These incentives, which are included in producement contracts as reliability improvement warranty (RIW) provisions, obligate the contractor to accomplish repair and replacement of failed equipment at a fixed price during operational use of the equipment by the Air Force. The contractor also quarantees the mean-time-between-failure of the equipment during the warranty period. The RIW provisions are projected to have a significant impact on avionic reliability.

N76-24609 Sumerlin (W. T.), Hazelwood, Mo. HIGH RELIABILITY DESIGN TECHNIQUES

W. T. Sumerlin. In AGARD. Avionics Design for Reliability Mar. 1976. 7 p. ref. (For availability see N76-24802. 15-38)

The general situation between the following two extremes in design techniques was considered: (1) commonplace techniques, with the constraints of holding a normal cost cailing and schedule, to provide higher reliability than would otherwise be expected, and (2) special and unusual techniques, with greatly extended costs and schedule, to produce much higher reliability. The objective under study was to attain a preferred balance between reliability and all competing factors such as performance. cost, schedule, etc. This requires a thorough understanding of the need for the desired reliability and the probability of its attainment under various trades and compromises. It was concluded that adherence to the discussed techniques and their intent will generally lead to the attainment of optimum reliability prior to the need for a quantitative reliability verification test. and the question of reliability growth during the development program becomes academic.

N76-24810 Deutsche Forschungs- und Versuchsanstelt füer Luft- und Reumfahrt, Oberpfaffenhofen (West Germany). DesSign OF ELECTRONIC GIRCUITS AND COMPONENT SELECTION FOR HIGH RELIABILITY

Walter Schambeck In AGARD Avionics Design for Reliability Mar. 1976 14 p. refs (For availability see N76-24502 15-36)

Rules were given for the selection of components for high reliability applications. Determining the suitable technology, part derating factors and then the selection or writing of specifications for parts procurement are described. The necessity of precap visual inspection by the user for high reliability applications is emphasized. The use of plastic IC's for HI-REL applications and a new development in this field is discussed. The second part is concerned with the design of reliabile circuits. Precautions to be taken against voltage and current overloading and the selection of the proper supply voltage are described. The use of MRI and LSI and synchronous operation is suggested to increase the reliability. Noise immunity and its influence on reliable operation is discussed. Finally redundancy versus screening and the cost of reliability are considered.

CASE HISTORY OF SOME HIGH RELIABILITY DESIGNS FOR AVIONIC SYSTEMS

J. A. Garnier and D. Reneric In AGARD Avionics Design for Reliability Mar. 1976 23 p. In FRENCH and ENGLISH (For availability see N76-24802 15-38)

Four methods developed to obtain high reliability with avionics equipment were described and illustrated. These methods deal with the following areas: (1)components, efforts are directed towards the achievement of manufacturing processes leading to high reliability devices, (2) reliability prediction: appropriate calculations are carried out to analyze the stresses to which components are submitted and to improve circuit design, (3) reliability and burn-in tests: their purpose is to reveal early operation defects and systematic failures, as well as to give an estimation of reliability close to the operational value, and (4) reliability clauses, guaranteed reliability or contractual maintenance clauses ensure that the aim in view has been reached. The main results of a study simed at analyzing the efficiency of these methods were then presented, based on a cost-reliability standpoint, for a particular example. Finally, the essential lessons learned from the application of these methods to known equipment were brought out

N76-24613 Deutsche Forschungs- und Versuchsanstelt füer Luft- und Raumfahrt, Oberpfaffenhöfen (West Germany). RELIABILITY TESTING OF ELECTRONIC PARTS

Walter Schamback In AGARD Avionics Design for Reliability Mar. 1976 18 p. refs (Fcr availability see N76-24602 15-38)

A survey of the environmental, physical and electrical tests, which are necessary to establish the reliability of electronic parts, is given. Special emphasis is placed on the testing of semiconductors. All the tests are described together with the failure they can detect in parts. Within these three categories of tests, nondestructive and destructive ones are distinguished. Although most popular tests are mentioned, special emphasis is placed on tests not so widely used yet, such as high stress tests, acoustical particle detection, thermal mapping by means of liquid crystals and the test of input protection directis of MOS Ic's. The need for visual inspection as a means of improving the quality of components is discussed. Product analysis as a means of evaluation of the parts manufacturar's capability is described in detail.

FRACTURE REGIMES

J. i. Bluhm In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 14-17 refs (For availability see N74-23413 14-32)

An analysis of the effects of ambient conditions on the fracture characteristics of materials is presented. A schematic diagram is provided to show range of applicable strength approaches. Stress-strain diagrams are developed of the limit stresses in notched plates and notched cylinders in tension. The considerations for fracture characteristics are examined with respect to: (1) linear fracture mechanics, (2) limit design for temperature extremes, and (3) transition approaches based on various structural analysis tests. The effect of superimposed hydrostatic pressure

on strain to fracture and the effects of temperature and/or strain rate are illustrated. The variation in stress state in the vicinity of a notch in a thick plate is analyzed.

THE USE OF FRACTURE MECHANICS PRINCIPLES IN THE DESIGN AND ANALYSIS OF DAMAGE TOLERANT AIRCRAFT STRUCTURES

Howard A. Wood In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 18-31 refs (For availability see N74-23413 14-32)

The application of fracture control principles to aircraft design in order to produce safer structures is discussed. The mechanical and physical properties of the construction materials which are capable of modification to produce the desired strength are discussed. The selected of materials for airframes is based on requirements established through actual failure experience and service life data. The nature of the requirements and allowances in their application are defined. Tables of data are provided to show the inspection requirements for cases of: (1) slow crack growth structure, (2) crack arrest structure, and (3) fail-safe

N74-23418 George Washington Univ., Washington, D.C. BASIC CONCEPTS IN FRACTURE MECHANICS

John Eftle, Douglas L. Jones, and Harold Liebowitz In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 32-73 refs (For availability see N74-23413 14-32)

A review of fracture mechanics is presented highlighting the strengths and limitations and establishing dome perspective of its relationship to the general fracture process. The importance of nondestructive inspection as one of several potential safegurads against failure by fracture is stressed. The subjects discussed include: (1) macroscopic classification of fracture. (2) linear elastic fracture mechanics, (3) fracture toughness in semibrittle fracture, (4) applications of fracture mechanics concepts, and (5) fatigue crack growth characteristics.

N74-23419 Army Materials and Mechanics Research Center, RESISTANCE METHOD

J. I. Bluhm In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 74-88 refs (For evallability see N74-23413 14-32)

A method of determining the strength of materials based on the resistance to fracture with increasing crack length is described. The criteria for stable crack growth for a variety of specimens for both load controlled and/or displacement controlled systems are expressed by a mathematical model. The various conditions which can affect the resistance to fracture of a material are analyted. Curves are developed to show: (1) schematic resistance/energy release rate changes in crack length, (2) constant load/constant deflection energy release rate curves for a tension specimen, and (3) constant load/constant deflection energy release curves for a bending specimen.

N74-23420 Army Materials and Mechanics Research Center. Watertown, Mass.

THE KUHN-HARDRATH METHOD

J. I. Bluhm In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 89-94 refs (For availability see N74-23413 14-32)

A procedure for determining the residual strength of a structural member which contains a damaged area is discussed. The damage covers the spectrum from a notch to its degenerate and generally most severe configuration, which is a crack. The method starts with an expression for the elastic stress concentration and recognizes that the maximum effective stress from a fracture point of view is not merely the nominal stress multiplied by a stress concentration factor. Instead, a concept is introduced to attempt to account for the microscopic heterogeneity of the material. The theoretical considerations are supported by mathematical models. Curves are developed to show the energy relations for fast and slow crack growth and the relation between sheet width and residual strength.

N74-23421 Army Materials and Mechanics Research Center, Watertown, Mass.

CRACK PROPAGATION LAWS

J. I. Bluhm In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 95-109 refs (For availability see N74-23413 14-32)

A numerical analysis of the principles of crack propagation is presented. Mathematical models are developed to show the relations between cyclic crack growth rates to various functions of the instantaneous crack length and the alternating stiess. The affects of programmed and random loading on the stability of airframes are analyzed and mathematical dependences are reported. The influences of geometry and/or structural considerations on structural stability are investigated.

N74-23422 Cornell Univ., Ithaca, N.Y. ENVIRONMENTAL EFFECTS IN FRACTURE

H. H. Johnson In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 110-117 refs (For availability see N74-23413 14-32)

The characteristics of environmental cracking of strotals structures are presented. A test method for evaluating the susceptibility of a structure to environmental cracking is described. The application of linear elastic fracture mechanics to predict and interpret environmental cracking phenomens when crack propagation is the controlling feature is discussed. Curves are developed to show (1) a comparison of threshold stress intensities for three specimen configurations (2) constant crack growth rate in a constant stress intensity test, (3) crack growth rate varius field intensity, and (4) correlation of hydraulic activator and surface flawed specimen results.

N74-23423 Army Materials and Mechanics Research Center, Watertown, Mass. SUMMARY OF LIMITATIONS

J.). Bluhm. In AGARD. Fracture Mechanics of Aircraft Structures. Jan. 1974. p. 118-120. refs. (For availability see: N74-23413. 14-32).

The limitations affecting the applicability of mechanics to the fracture process are discussed. Methods for conducting stress state analysis are presented to include the following: (1) crack opening displacement, (2) resistance mathod, and (3) the Kuhn-Hadrath method. A list of factors which influence the crack propagation behavior is developed.

David Brook In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 167-180 (For availability see N74-23413 14-32)

The factors which affect the application of fall-safe techniques in aircraft design are discussed. The load-time histories and flight-load profiles are analyzed on the basis of the following:

(1) gust, maneuvers, and taxiing loads were assumed to occur as one cycle, (2) the sequence of loads was assumed random without correlation, and (3) flight profiles may differ from flight to flight, especially with respect to the large cycles and the number of cycles. Methods for estimating fatigue crack propagation are analyzed. The crack propagation life for various materials is tabulated.

The residual strength of sheet structures under conditions of plane stress is discussed. The basic fracture behavior of a stiffened panel is explained. The principles for calculating the residual strength of aircraft structures are analyzed. Curves are developed to show the residual strength of stiffened and unstiffened panels for various configurations. Mathematical models of the factors involved in residual strength calculations are provided.

N74-23428 Douglas Aircraft Co., Inc., Long Brach, Calif THE APPLICATION OF FRACTURE MECHANICS IN THE DEVELOPMENT OF THE DC-10 FUSELAGE

T. Swift In AGARD Fracture Mechanics of Aircraft Structures
Jan. 1974 p 226-287 refs (For availability see N74-23413
14-32)

The degree of damage tolerance used in the design of the DC-10 fuselage pressure shell is discussed with reasons for its selection. Analysis methods are presented for the prediction of the residual strength of damaged, stiffened panels, based on the Matrix Force solution of an idealized structure combined with fracture mechanics equations. The effects of attachment flexibility, which play an important part in the residual strongth of damaged structure, are accounted for. Crack growth retardation due to the plastic zone formed on high load cycles and its effect on propagation under spectrum loading is discussed. It is shown that the stress intensity at the threshold of slow stable growth is not only a material property but depends almost entirely on past load history. A description of the development test program to verify the analytical techniques and to substantiate the fail-safe strength of the fuselage shell is given together with the results of many of the tests. HEAVY SECTIONS

W. T. Kirkby In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 288-293 refs (For availability see N74-23413 14-32)

Methods for predicting the residual strength of relatively thick structures under plane strain conditions are presented. The problems are discussed in relation to heavy members with surface flaws, corner cracks at holes, and other natural cracks. Practical exemples of the application of the procedure are provided. Mathematical models are included to show the relation of the various parameters involved in the structural analysis. Author

AEROSPACE PRESSURE VESSELS

C. F. Tiffany in AGARD Fracture Mechanics of Aircraft Structures

Jan. 1974 p 294-313 refs (For availability see N74-23413

14-32)

During the development of the many pressure vessels used in the Apollo Program several serious failures were encountered. In some cases through-the-thickness cracks formed and the vessels leaked. In other cases, small surface or embedded flaws grew to critical size prior to growing through the chickness of the vessel wall and catastrophic failure. Several of the different types of pressure vessel failures which have been encountered are reviewed. A discussion of the important considerations and the general technical approach being used to prevent failures in the future are presented. This encompasses many considerations ranging from Initial material selection through the final acceptance of individual batches of propellant based on the results of fracture specimen tests. Examples of static fracture toughness and subcritical flaw growth data, which have been obtained on various research programs are included. Cyclic lives, times to failure and flaw growth rates are discussed in the context of linear elastic crack tip stress intensity factors. It is shown how the proof test is used to provide assurance of subsequent service life for both thick and thin walled vessels, and test procedures are recommended which should minimize potential damaging effects of the test which can occur as a result of flaw growth.

AN EXAMPLE OF A METHOD FOR PREDICTING FAILURE G. H. Haslam In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 314-324 refs (For availability see N74-23413 14-32)

A method is presented for estimating the life to failure of a cylindrical pressure vessel subjected to repeated internal pressure. Design curves are obtained by which the fatigue life of such a cylinder may be estimated from a knowledge of the transverse uniaxial fatigue limit and fracture roughness properties of the cylinder material, as well as the diameter ratio of the cylinder and the repeated pressure. Examples are given of the application of the method and close correlation is demonstrated between estimated and actual behaviour

BERVICE FAILURES AND LABORATORY TESTS

W. Barrois In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 325-345 refs (For availability see N74-23413 14-32)

The significant differences between structural analyses conducted in the laboratory and those conducted under service conditions are compared. Low temperature brittleness and hydrogen embrittlement of steels are used as examples. intergranular or stress corresion of aluminum alloys are reviewed in relation to various causes of service or manufacturing damages. The main objectives of structural tests are defined. Curves are developed to show the fracture toughness of steel sheets as a function of treatment and test temperature. Photographic samples of specific types of structural failure are included.

A SHORT SURVEY ON POSSIBILITIES OF FATIGUE LIFE ASSESSMENT OF AIRCRAFT STRUCTURES BASED ON RANDOM OR PROGRAMMED FATIGUE TESTS

W. Barrols In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 346-366 refs. Repr. from AGARD Conf. Proc. No. 118 (For availability see N74-23413 14-32)

The various physical parameters which are significant in the fatigue behavior of specimens and structures are reviewed. Several types of fatigue tests are analyzed to show their applicability. A short survey is made of present prediction methods of structure fatigue life from fatigue tests of components, assemblies, and structures undergoing constant amplitude loadings. The case of random loadings is also discussed. The possibility of test acceleration by increasing general loading itensity

N74-23434 Technische Hogeschool, Delft (Netherlands). OUTLOOK, FUTURE DEVELOPMENTS

David Brook In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 367-369 (For availability see N74-23413 14-32)

The factors which influence the design of fall-safe systems are discussed. It is stated that many of the shortcomings in fail-safe design are caused by insufficient knowledge of fracture and fatigue mechanisms. For successful fail-safe operation, the results of tests should be documented with respect to critical locations, crack propagation rates, and residual strongth. The procedures for conducting tests which will provide the data required for fail-safe design are defined.

EXPERIMENTAL TECHNIQUES FOR DETERMINING FRACTURE TOUGHNESS VALUES

Walter Schuetz and Wolfram Oberparleiter In AGARD Fracture Meghanics of Aircraft Structures Jan. 1974 p 371-394 refs (For availability see N74-23413 14-32)

The Standard Method of Test for Plane Strain Fracture Toughness of Metallic Materials and the Standard Method of Sharp Notch Tension Testing of High Strength Sheet Materials, are described and some details which are important for carrying out the test are discussed. A series of nonstandard test methods are explained which mainly use different specimen shapes. Advantages and disadvantages of these test methods are discussed and comparisons of the test results with results obtained from the ASTM standard specimen are made. Also test equipment for testing fracture toughness of waldments, under environmental conditions (low temperature, sait water corrosion) and high strain rates are described.

RELIABILITY OF THE DETECTION OF FLAWS AND OF THE

DETERMINATION OF FLAW SIZE
Ekkert Knorr In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 395-412 refs (For availability see N74-23413 14-32)

Laboratory investigations concerning reliability of crack detection and determination of crack size which represent the state of the art are described. All three are typical applications of nondestructive inspection to structural parts of aircraft: (1) inspection of flat surfaces with fatigue cracks, using uitrasonic. X-ray, dye penetrant, magnetic particle and eddy current methods, (2) crack detection below rivet heads with an ultrasonic shear wave technique, and (3) crack detection in bore holes of a forged part using a manual eddy current method. The second and the third one analyzed for statistical evaluation of probability of success. An evaluation of the conventional NDI-methods regarding reliability is performed.

NONDESTRUCTIVE TESTING (NDT) AND FRACTURE MECHANICS

Enrico Bolls In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 413-417 refs (For availability see N74-23413

The basic concepts of nondestructive testing (NDT) are reviewed in relationship with fracture mechanics concepts. The necessity of correlating basic differences between ordinary destructive mechanical tests and NDT is considered. The use of NDT for assessment of integrity of sircraft components and structures, after fabrication and during service life is discussed. Inherent limitations of NDT and necessity of interdepartmental team work are reviewed. General information on routine and advanced methods is included.

Author

N74-23438 Aerojet Solid Propulsion Co., Sacramento, Calif. DETECTION AND DETERMINATION OF FLAW SIZE BY ACQUISTIC EMISSION

C, E. Hartbower In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 419-473 refs (For availability see N74-23413 14-32)

Available acoustic emission instrumentation systems are so sensitive that it is possible to detect each stage of the failure process starting with deformation (dislocation pileups), crack propagation and, finally, the onset of instability all in real time. In the second and third stage of the failure process, it is possible by triangulation to locate the source of the signal. In some applications, the practical limitation for use of acoustic emission as a nondestructive inspection method has been and will continue to be extraneous noise. However, most noise problems are solved by the effective use of band-pass filters or special isolation techniques involving computer solutions. The use of acoustic emission as a nondestructive inspection technique has been under development for over a decade. The technique is based upon the elastic energy which is spontaneously released when a material undergoes plastic deformation and/or cracking. Thus, acoustic emission constitutes a unique nondestructive inspection method in that the material defect when propagating, transmits its own signal, with the sensor acting as the receiver. The material undergoing crack growth both generates and transmits the signal (acoustic emission) which then can be detected by suitable Instrumentation and the source located using seismic tech-Author niques.

AN ANALYSIS OF A TEST FATIGUE FAILURE BY FRACTO-

GRAPHY AND FRACTURE MECHANICS
C. J. Peel In AGARD Fracture Mechanics of Aircraft Structures Jan. 1974 p 503-508 refs (For availability see N74-23413 14-32)

The fracture surfaces of two fatigue cracks, that had caused the failure of an engine impeller during a fatigue substantiation test, were examined by electron microscopy to find the number of fatigue crack growth cycles. This was done by measuring the specings of fatigue striations on the fracture surface as a function of crack depth and by subsequent integration of the striction apacing versus crack depth expression. The measured striction spacings were compared with laboratory grack growth data to determine the fatigue stress intensity range as a function of crack depth and hence the fatigue stress range. The number of crack initiation cycles was then found by comparing the fatigue stress range and number of crack growth cycles with further laboratory data and the total fatigue life was calculated to have been approximately 50,000 cycles. This identified the fatigue loading that had caused the failure as having been the 29179 cycles of engine acceleration and deceleration that had been applied during the test.

TYPICAL PLANE STRAIN FRACTURE TOUGHNESS OF AIRCRAFT MATERIALS

W. T Matthews In AGARD Fracture Mechanics of Aircraft Structure Jan. 1974 p 509-579 refs (For availability sea N74-23413 14-32)

The fracture toughness values of aircraft metals are expressed In terms of linear elastic fracture mechanics. The general tabulation includes only values measured under plane strain conditions. These plane strain K sub IC values have been obtained by the ASTM E399-72 Standard Method of Test for Plane Strain Fracture Toughness Testing of Metallic Material or a similar method. This data compilation includes materials manufactured in the U.S.A. and Europe. Factors involved in the selection and interpretation of the K sub IC values will be discussed in the latter sections of this introduction

LOW CYCLE HIGH TEMPERATURE FATIGUE

Aug. 1974 149 p refs in FRENCH and ENGLISH Presented at the 38th meeting of the Struct, and Mater. Panel, Washington, D. C., 21-26 Apr. 1974

(AGARD-CP-155) Avail: NTIS HC \$5.75

The operating conditions of aircraft are discussed in terms of propulsive efficiency, especially insofar as fatigue and creep phenomena affect the performance of engines operating at high and variable temperatures, and under cyclic stresses. Low cycle high temperature fatigue studies were conducted to obtain data related to these questions. For individual titles, see N75-10486 through N75-10494.

PRECISION IN LCHTF TESTING

E. M. Smith In AGARD Low Cycle High Temp. Fatigue Aug-1974 19 p refs (For availability see N75-10487 01-39)

Fast and accurate temperature control in low cycle high temperature fatigue (LCHTF) testing depends on an accurate sensitivity to changes in stress and temperature levels, exidation, direction, and rates of loading. Extremities of the possible test spactrum are described in terms of constitutive testing and component testing. An evaluation of thermal and stress fields within the specimen geometry, selection of appropriate heating and cooling methods, and assessment of precision of measurement under thermal and mechanical transients were all involved in the constitutive behavior testing. Coupon testing, utilizing precisely controlled thermal shocks, was used to measure component response to LCHTF conditions.

THE EFFECT OF CYCLE PANAMETERS ON HIGH TEMPERA-

TURE LOW CYCLE CATIGUE
G. F. Harrison and M. G. Cockcroft In AGARD Low Cycle High Temp. Fatigue Aug. 1974 15 p. rafs. (For availability see N76-10487 01-39)

The types of information required by engine designers in the area of high temperature low cycle fatigue engine parameters are summarized, particularly concerning temperature effects, frequency and hold-time effects, and the effects of strain cycling and stress cycling. The choice of testing method is dependent on the type of analysis employed when making use of the data and the various possible approaches are compared. It is suggested that in high temperature situations there is often advantage in regarding fatigue as a creep-dominated process. Some gaps in the present state of knowledge are indicated Author

MULTIAXIAL FATIGUE. PRESENT AND FUTURE METHODS OF CORRELATION

Erhard Krempl In AGARD Low Cycle High Temp. Fatigue Aug. 1974 13 p. refs (For availability see N75-10487 01-39).

Multiaxial fatigue fracture criteria are viewed as surfaces in stress (strain) space which can exhibit isotropy or anisotropy. A quadratic form of the proposed equation includes the von Mises. the Sines and the Gough criteria. It is shown how this criterion can be fitted to low-cycle fatigue data, and specific methods are suggested for the experimental determination of these constants. The criterion exhibits a linear mean stress (strain) effect and the tention-torsion ratio must be less than two. Tests necessary for the determination of the orthotropic constants are outlined. A possible extension to variable amplitude loading is suggested

N75-10493 Connecticut Univ., Storrs. Dept. of Metallurgy. LIFETIME PREDICTION METHODS FOR ELEVATED TEM-PERATURE FATIGUE

A. J. McEvily and S. R. Crosby 'n AGARD Low Cycle High Temp. Fatigue Aug. 1974 18 p. refs (For availability see N75-10487 01-39)

Methods for lifetime prediction at elevated temperatures can be categorized as either: (1) parametric; (2) damage summation: (3) strainrange partitioning; or (4) frequency modification. The capabilities and limitations of these various approaches are discussed, and the problem of extrapolation beyond laboratory experience is considered.

N75-10494 Pratt and Whitney Aircraft, Middletown, Conn. Materials Engineering and Research Lab DESIGN PROCEDURES FOR ELEVATED TEMPERATURE LOW-CYCLE FATIGUE

C. H. Wells In AGARD Low Cycle High Temp. Fatigue 1974 17 p refs (For availability see N75-10487 01-39)

The state of the art review of component design against low-cycle fatigue failure at elevated temperature, covers the areas of failure criteria, nondestructive inspection, constitutive behavior, pradiction of crack initiation and propagation lifetime, applicability of linear elastic fracture mechanics, and structural verification. Special problems posed by gas turbine applications are discussed, along with major gaps in understanding and techniques. Chief annung these are the nondestructive characterization of surfaces and internal flaws, definition of the limitations of fracture mechanics in the regime of intergranular cracking, the prediction of mean stress and cyclic creep, and the experimental verification of analytical procudures at high temperature.

N75-12357# Advisory Group for Aerospace Research and Development, Paris (France).

STRUCTURAL OPTIMIZATION

Sep. 1974 94 p. refs. Lecture series presented at Hampton, Va., 10-11 Oct. 1974, Duesseldorf, 14-15 Oct. 1974, and London, 17-18 Oct 1974

(AGARD-LS-70) Avail: NTIS HC \$4.75

A series of reports are presented to inform structural design engineers on the latest developments in partical design optimization methods. Emphasis is placed on the applications and use of these methods in practical design organizations. The subjects considered include the following: (1) use of optimality criteria methods for large scale systems. (2) approximation concepts for structural synthesis, (3) geometric programming methods for structural optimization, and (4) sizing of complex structure by the integration of several different optimal design algorithms. For individual titles, see N75-12358 through N75-12362.

N75-12358 Air Force Flight Dynamics Lab., Wright-Patterson

USE OF OPTIMALITY CRITERIA METHODS FOR LARGE SCALE SYSTEMS

L. Berke and N. S. Khot In AGARD Structural Optimization Sep. 1974 29 p. refs (For evailability see N75-12357 03-39)

The development of finite element techniques enabled the structural engineer to analyze to analyze the extremely complex structural systems typical of modern serospace vehicles. The trend now is towards automated design methods. In the case of large structural systems, optimality criteria methods, now in an advanced stage of development, appear to be the most practical for the problem of automated sizing. A brief historical review of optimality criteria methods is given. The general optimality criteria of equal cost of improvement for every active design variable is derived. The problem of multiple active constraints is discussed and solution alternatives are pointed out. As special cases, optimality criteria for generalized deflection constraints, general instability and dynamic response are derived and examples

SOME APPROXIMATION CONCEPTS FOR STRUCTURAL SYNTHESIS N75-12359* Catifornia Univ., Los Angeles.

L. A. Schmit, Jr. and B. Farshi In AGARD Structural Optimization Sep. 1974 8 p. refs. Repr. from AIAA J., v. 12, no. 5, May 1974 p 692-699 Presented at the AIAA/ASME/SAE 14th Struct, Structural Dyn., and Mater. Conf., Williamsburg, Va., 20-22 Mar. 1973 (For availability see N75-12357 03-39) (Grant NGR-05-007-337)

(NASA-CR-140937; Paper-73-341) CSCL 13M

An efficient automated minimum weight design procedure is presented which is applicable to sizing structural systems that can be idealized by truss, shear panel, and constant strain triangles. Static stress and displacement constraints under alternative loading conditions are considered. The optimization algorithm is an adaptation of the method of inscribed hyperspheres and high efficiency is achieved by using several approximation concepts including temporary deletion of noncritical constraints, design variable linking, and Taylor series expansions for response variables in terms of design variables. Optimum designs for several planar and space truss examples problems are presented. The results reported support the contention that the innovative use of approximation concepts in structural synthesis can produce significant improvements in efficiency.

N75-12360 Liverpool Univ. (England). THE USE OF GEOMETRIC PROGRAMMING METHODS FOR STRUCTURAL OPTIMIZATION

Andrew B. Templemen In AGARD Structural Optimization Sep. 1974 17 p refs (For availability see N75-12357 03-39)

Structural design problems may be classified into two types. (1) the detailed design of components and (2) the design of assemblages of idealised components. The paper demonstrates that geometric programming is suitable for a wide range of optimum design problems in both these classes. The mathematics of the geometric programming method is explained with the aid of a simple example and a computer program for large problems is described. It is shown that component design characteristically gives rise to the type of functions best suited to geometric programming. Examples are presented of the use of peometric programming for the optimum design of several kinds of structural components. The design of an integrally stiffened compression panel is examined in more detail. The paper demonstrates that geometric programming can also be used for the optimum design of complete idealised assemblages of components. Examples are given of the minimum weight design of trusses.

Langley Research Center, Langley Station, Va. SIZING OF COMPLEX STRUCTURE BY THE INTEGRATION OF SEVERAL DIFFERENT OPTIMAL DESIGN ALGON-

Jaroslaw Sobieszczanski In AGARD Structural Optimization Sep. 1974 19 p refs (For availability see N75-12357 03-39)

Practical design of large-scale structures can be accomplished with the aid of the digital computer by bringing together in one computer program algorithms of nonlinear mathematical programing and optimality criteria with weight-strength and other so-called engineering methods. Applications of this approach to eviation structures are discussed with a detailed description of how the total problem of structural sizing can be broken down into subproblems for best utilization of each algorithm and for efficient organization of the program into iterative loops. Typical results are examined for a number of examples.

A DISCRETIZED PROGRAM FOR THE OPTIMAL DESIGN OF COMPLEX STRUCTURES

James R Batt and Ronald A. Gellatly In AGARD Structural Optimization Sep. 1974 15 p refs (For availability see N75-123h/ 03-39)

More economical and more flexible procedures for structural optimization of large scale systems have been sought. A new approach to determine the minimum weight of such systems has been developed, is discrete in nature, and is labeled the since-search technique. An essential element of the technique is the use of data banks which contain minimum weight and assecrated using classical methods of aptimization. An additional facet of the technique is the use of simplified engineering analysis methods during the redesign phase of the optimization cycle. Herein lies the efficiency of the sieve-search technique. The method was successfully applied to the design of an extensive class of surface effect vehicles and is shown through application to the design of thermal protective systems and associated wing substructure.

MECHANICAL PROPERTY TESTING OF HIGH TEMPERA-TURE MATERIALS

R W Davidge and J Massmann Dec 1975 34 p. refs (AGARD-R-634) Avail NTIS HC \$4.00

The Structures and Materials Panel recently initiated a new activity dealing with the field of high temperature materials. Soveral exploratory papers were heard covering various aspects of this field, to aid in determining the desired direction of the new activity. Two of these papers were considered particularly noteworthy. The first deals with the mechanical proportios and design data of ceramic components for engineering applications Materials science considerations are emphasized with brief reference being made to the engineering aspects. Areas requiring further development are also covered. The second paper. dealing with stress and strein calculations, shows the application of the finite element method to a structural analysis and lifetime prediction problem, and includes the calculation of stress and strain distribution at critical locations. Stress concentration factors in specimens of linear and nonlinear material, different types of yield criteria, use of Neuber and the Hardrath and Ohman Theories are examined and results are compared with the finite element method. Plasticity and creep influences are considered individual titles, see N76-16493 through N76-16494.

N76-16493 Atomic Energy Research Establishment, Harwell (England) Materials Development Div THE MECHANICAL PROPERTIES AND DESIGN DATA FOR ENGINEERING CERAMICS

R W Davidge In AGARD Mach. Property Testing of High Tamp Mater Dec 1975 p 1-9 refs (For availability see N76 16492 07-39)

Developments in understanding the mechanical proporties of ceramics from a materials science viewpoint, and in the generation of design data for ceramics of direct applicability to originize in applications are discussed. General recommendations for further research are made.

CALCULATION OF STRESS AND STRAIN DISTRIBUTION AT CRITICAL LOCATIONS, TAKING INTO ACCOUNT PLASTICITY AND CREEP

Diergon Mussmann. In AGARD. Mech. Property Testing of High Temp Mater. Dec. 1975 p. 10-29 (For availability see N76-16492 07-39).

The finite element method was applied to a particular attrictural analysis problem, the calculation of the stress and strain distribution at critical locations, which occurs in life time prediction. Some of the types of elements currently available, the selection of economical elements, and the required accuracy of the calculated results are discussed. The calculated stress concentration factor of a specimen containing a hole is presented for linear and nonlinear materials and different types of yield criteria are briefly discussed. The use of the Neuber and the Hardrath and Ohmen Theories to determine the stress and strain concentration factor for nonlinear material behavior is examined, and a companion of the results of these different theories and the Finite Element Method is given. The influence of plasticity and creep is also considered and the stress and strain concentration factor is shown as a function of creep time.

N76-19471# Advisory Group for Aerospace Research and Development, Paris (France).

SPECIALISTS MEETING ON IMPACT DAMAGE TOLER-ANCE OF STRUCTURES

Jan 1978 202 p refs In ENGLISH and FRENCH Paper presented at 41st Meeting of the Struct and Mater. Panel, Ankers, 28 Sep 3 Oct 1975 (AGARD CP 188. ISBN-92-835-0154-3) Avail NTIS

(AGARD CP 188) ISBN 92-835-0154-3) Avail NIIS HC \$7.75

Among the subjects covered in this exploratory conference were blast effects, the type of damage produced by different projectiles, the failure characteristics of the structure under load and its residual strength and life after damage; the relationship between spread of damage, materials used, and detail design features, the degree of projectile penetration and the related hydraulic ram effect in fuel tanks, and distribution of size, velocity and direction of engine debris fragments and their effect on structure. The relationship to improved aircraft damage tolerance of such factors as the use of armor and deflectors, the employment of modified engine design (to cause blade failure to be more likely than disc failure and to contain a large portion of the resultant debns), the effectiveness of analysis of damaged structures, and the utilization of methods of improvement of overall aircraft layout are also considered. For individual titles, see N76-19472 through N76-1948?

N76-19472 Boeing Aerospace Co., Seattle, Wash Research and Engineering Div STRUCTURAL INTEGRITY REQUIREMENTS FOR PROJECTILE IMPACT DAMAGE; AN OVERVIEW

J. G. Avery, T. R. Porter, and R. W. Lauzze (AFFDL). In AGARD Specialists Meeting on Impact Damage Tolerance of Struc. Jan 1976. 30 p. refs (For availability see N76-19471.10-39).

Aircraft can be exposed to projectile impacts from several sources, including military weapons, hailstones, pebbles, and debris from engine failures. In spite of the importance of the projectile damage threat to many types of aircraft, this category of damage is addressed in only a limited degree by existing design guidelines and specifications. There is a growing body of research results becoming available, and attention is being directed toward making this information usable to designers. The only means of doing this is to integrate projectile damage tolerance considerations within the existing structural design process. A design methodology for projectile damage tolerance and some of the research results available for implementing the methodology are sum marized.

N76-19473 Industrieanlagen-Betriebsgesellschaft mbH. Ottobrunn (West Germany) STRUCTURAL ANALYSIS OF IMPACT DAMAGE ON WINGS Juergen Massmann In AGARD Specialists Meeting on Impact Damage Tolerance of Struc. Jan. 1978–27 p. refs (For availability see N76-19471-10-39)

A recently-developed structural strength model is described, and the functions and characteristics of a damage model are examined. A shock wave model and how it analytically determines the dynamic response of a pressurized flat plate is also presented. Test and finite element results are compared with model-predicted results in order to determine model credibility. The pressures resulting from the detonation of ammunition are discussed, and the contributions of each of the pressure components to the entire response are illustrated. Some advantages of an advanced fragment model are mentioned, and the results from such a model are compared with appropriate test data. Applications of the different damage submodels with respect to a honeycomb Author.

N76-19474 Naval Weapons Center, China Lake, Calif. FLUID DYNAMIC ANALYSIS OF HYDRAULIC RAM

Eric A. Lundstrom and Wallace K. Fung. In AGARD. Specialists Meeting on Impact Damage Tolerance of Struc. Jan. 1976. 10 p. refs (For availability see N76-19471 10-39).

A model was developed for predicting fluid pressure fields generated by tumbling military ammunition. Derivation of the model is described, and comparison with experimental data is shown. Agreement of the model was quite good with shots fired into a test cell with 0-degree obliquity. Significant deviation of the model from experiment was obtained with 30-degree obliquity shots.

STUDY OF CERTAIN IMPACT PROBLEMS ON AIRCHAFT STRUCTURES [CALCUL DE QUELQUES PROBLEMES D'IMPACT SUR DES STRUCTURES AERONAUTIQUES]

C Petiau In AGARD Specialists Meeting on Impact Damage Tolerance of Struc. Jan. 1976–14 p. in FRENCH (For evailability see N76-19471–10-39)

After reviewing some of the finite elements, methods used for calculating impacts and transitory responses, the possibilities of application in the following cases are examined: (1) response of structure upon impact of a projectile on an armor-plate, (2) response of structures to forces due to explosion blast, and (3) calculation of hard landings, catapulting and taxling. Practical calculation of the residual strength of locally damaged structures is also considered.

COMPUTER METHOD FOR AIRCRAFT VULNERABILITY ANALYSIS AND THE INFLUENCE OF STRUCTURAL DAMAGE ON TOTAL VULNERABILITY

Dister Kardels In AGARD Specialists Meeting on Impact Damage Tolerance of Struc. Jan 1976 21 p refs (For availability see N76-1947) 10-391

Methodology consists of two besic computer models, the socialist ammunition and target models. These models are so constructed that the evaluation of ammunition types such as AP. API. HEI with both impact and proximity fuzes, and fragmenting warheads is possible, as is a detailed vulnerability assessment of a porticular aircraft. Various submodels interact in order to show the different types of possible outputs. A special emphasis is given to the influence of structural damage and aerodynamic capabilities on total aircraft vulnerability Some test data and model pradiction results are also graphically presented.

DAMAGE TOLERANCE OF SEMIMONOCOQUE AIRCRAFT
Donald F Haskell In AGARD Specialists Meeting on Impact
Damage Tolerance of Struc. Jan. 1976 12 p. ref (For availability
spe. N76-19471 10-39)

The simple theoretical method which was developed may be used to predict deformation, strain, and fracture of aircraft skin subjected to blast attack. Test results and predictions of the theory compare favorably. The method is used to analytically delineate the factors that significantly affect skin damage tolorance. For the conditions studied, these factors, in decreasing order of influence, are standoff distance, panel width, skin thickness, aspect ratio, skin ultimate strength, rivet spacing, and rivet hole diameter to skin thickness ratio. Test results of two types of semimonocoque helicopter tail booms damaged by bare explosive charges and small-calibler, high-explosive projectiles while under

simulated maximum flight load show that both skin and the skin stiffening system are important in the damage tolerance of these structures. Damage tolerance of these structures is proportional to the section modulus of the undamaged section and inversely proportional to the amount of skin removed from the structure by the damaging agent. It is also demonstrated that large increases in damage tolerance can be achieved by increasing longitudinal stiffness.

PROBABILITY OF PERFORATION OF AIRCRAFT STRUCTURES BY ENGINE FRAGMENTS [PROBABILITE DE PERFORATION D'UNE STRUCTURE D'AVION PAR DES DEBRIS DE MOTEURS]

Michel Huret In AGARD Specialists Meeting on Impact Damage Tolerance of Struc. Jan. 1976–12 p. in FRENCH (For availability see N76-19471-10-39)

An analytical approach was presented by which the probability of perforation of aircraft structures by engine fragments may be determined, given a specific fragment ejection model provided by angine designers. Simplifying, realistic assumptions were made to keep the implementation practical. A mathematical model was derived, taking into account the geometry of the situation, the energy of the fragment and that of the target, and the contact relationship between the fragment and the target.

(AGARD-AG-160-Vol-7, ISBN-92-835-1215-4) Copyright. Avail NTIS HC \$8.00

Various subjects related to the application of strain gauges to airgraft structures were presented. These include: (1) introductory discussion, (2) physical properties of strain gauges, (3) measurement of resistance changes in strain guages, (4) error estimation for strain gauges with metallic measuring grids, (5) types of strain guages, (6) applications of strain gauges for static and dynamic short and long term measurements under normal conditions. (7) strain gauges for special applications, (8) use of strain gauges under extreme environmental conditions.
(9) instrumentation of two VAK 191 B aircraft with flight load measuring systems. For individual titles, see N76-25581 through N76-25589

N76-25561 Advisory Group for Aerospace Research and Development, Paris (France) STRAIN GAUGE MEASUREMENTS ON AIRCRAFT INTRO-

DUCTION

In its Strain Gauge Meas on Aircraft, Vol. 7 Apr. 1976 p 1-4 (For availability see N76-25580 16-39)

A comprehensive description of the different aspects of strain and load measurements on sircraft was given. After discussion of possible errors, the various types of strain gauges and adhesives are described Practical advice is given on their application. including a discussion on special cases. This is followed by a consideration of the strain gauge behavior under adverse environmental conditions (extremely low and high temperatures) Finally, an example is given of equipping an aircraft with a flight load measuring system

N75-25582 Advisory Gloup for Aerospace Research and Development, Paris (France PHYSICAL BACKGROUND

In its Strain Gauge Meas on Aircraft, Vol. 7 Apr. 1976 p. 5-18 (For availability see N76-25580 16-39)

The physical background of the strain gauge system was presented. One part of this system is the material to be tested The elementary laws of the behavior of metallic materials under load are described. The other important part is the measuring grid of the strain gauge. The fundamental correlations between the load on the measuring grid and its electrical behavior is described. Metallic as well as semi-conductor measuring grids are both discussed

THE MEASUREMENT OF THE RESISTANCE CHANGES OF STRAIN GAUGES

In Its Strain Gauge Meas on Ancraft, Vol. 7, Apr. 1976, p. 18-29 (For availability see N76-25580 16-39)

Selection of the most appropriate method of recording small resistance changes in stroin gauges when loads are applied was discussed. The basic equations underlying the electrical circuits involved were given and discussed. Special emphasis was placed on the Wheastone bridge circuit, which is the predominant measuring circuit for strain gauge measurements. The following aspects were elaborated (1) current and voltage distribution, (2) choice of the supply voltage with respect to power dissipation, (3) choice of the output signal conditioning equipment. (4) power dissipation in the bridge resistors. (5) behavior of the Wheastone bridge in unbalanced conditions, and (6) bridge balancing and compensation

ERROR ESTIMATION FOR STRAIN GAUGES WITH METALLIC MEASURING GRIDS

In its Strain Gauge Meas on Aircraft, Vol. 7, Apr. 1976, p. 29-33 (For availability see N76-25580 16-39)

The various factors that must be considered in error estimation for strain gauges with metallic measuring grids were discussed. These include: (1) resistance tolerances, (2) gauge factor tolerances and transverse strain sensitivity, (3) error caused by hysteresis and non-linearity, (4) maximum static elasticity of strain gauges, (5) creep effects, (6) temperature coefficient, (7) fatigue strength, (8) thickness of the adhesive layer, (9) angular errors during application of the strain gauge, (10) stiffening effect due to bonding, (11) insulation resistance effect, and (12) averaging effect of the strain gauge over the entire measuring grid area. Estimates of the total error are given.

N76-25585 Advisory Group for Aerospace Research and Development, Paris (France). TYPES OF STRAIN GAUGES

In its Strain Gauge Meas, on Aircraft, Vol. 7, Apr. 1976 p. 33-37 (For availability see N78-25580 16-39)

The various types of strain gauges were classified and described. The several hundred different strain gauge configurations were assigned to one of the following basic types: (1) wire-grid strain gauges. (2) flat-coil gauges. (3) cross-bridge gauges. (4) metal-foil guages, and (5) strain gauges with metal supporting materials. The following supporting materials, their configuration, and properties were also discussed: paper, epoxy or phenolic resin, polyimidefoil, glass-fiber reinforced material, cellulose and metal foil (for large strains). Typical properties of some strain gauge groups were given. The new technology of Vapor-depositing strain gauges was briefly mentioned.

N76-25586 Advisory Group for Aerospace Research and Development, Paris (France).

APPLICATION OF STRAIN GAUGES TO STATIC AND DYNAMIC SHORT AND LONG TERM MEASUREMENTS UNDER NORMAL CONDITIONS

In its Strain Gauge Meas, on Aircraft, Vol. 7, Apr. 1976 p 37-45

(For availability see N76-25580 16-39)

The following factors that must be considered in the application of strain gauges to static and dynamic short and long term measurements under normal conditions were discussed: (1) technical and organizational boundary conditions, (2) material selection, (3) pretreatment of bonding areas (precleaning, mechanical, chemical). (4) adhesives (cold and hot setting), (5) special procedures (flame spraying, welding), (6) wiring technique, (7) protective materials, and (8) general instructions.

N78-25587 Advisory Group for Aerospace Research and Development, Paris (France) STRAIN GAUGES FOR SPECIAL APPLICATION

In its Strain Gauge Meas on Aircraft, Vol. 7 Apr. 1976 p 45-72

(For availability see N76-25580 16-39)

Various special applications for strain gauges, involving multi-axial measurements, were described. These include: (1) measurements of multi-axial strain conditions and the determination of mechanical stress conditions (using various rosettes), (2) measurement of strain behavior by means of strain gauge chains, (3) strain gauges for flexural strain measurements, (4) strain gauges for membrane stress measurements, (5) strain gauges for the determination of residual stresss, (6) stress gauges, (7) measurement of material fatigue, (8) measurement of large strains, (9) special procedures for strain gauge applications, (10) strain transformers. (11) geometrical arrangement and electrical interconnections to realize special measuring effects, (12) measurement of strain on and in fiber-reinforced components, (13) interconnection of strain gauge bridges for the measurement of defined load elements(structural measurements), (14) highfrequency strain measurement, (15) strain gauges of excessive length, and (16) interferometric strain gauges.

N76-25588 Advisory Group for Aerospace Research and Development, Paris (France)

USE OF STRAIN GAUGES UNDER EXTREME ENVIRON-MENTAL CONDITIONS

In its Strain Gauge Meas on Aircraft, Vol. 7. Apr. 1976 p. 72-78 (For availability see N78-25580 16-39)

A survey of the possibilities and limits of the strain gauge technique under extreme environmental conditions was given This includes (1) Use at extreme temperatures, (2) use under hydrostatic pressure, (3) use under nuclear radiation, (4) use in magnetic fields, and (5) use under vacuum conditions

Advisory Group for Aerospace Research and Development, Paris (France). INSTRUMENTATION OF TWO VAK 191 B AIRCRAFT WITH FLIGHT LOAD MEASURING SYSTEMS In its Strain Gauge Meas on Aircraft, Vol. 7 Apr 1976 p 78 138 refs (For availability see N76-25580 16-39)

The instrumentation of the VAK 191 B STOL sircraft with strain gauge systems was described in some detail. The following measuring sections were planned for each aircraft. 4 measuring sections in the wing (2 port and 2 starboard), 2 measuring sections in the horizontal tail (1 port and 1 starboard). 1 measuring section in the vertical tail, 1 measuring section in the rear fuselage, and a number of measuring points on the landing gear and flight controls. A requirement of approximately 2,000 single strain gauges (or correspondingly smaller quantities of blaxial rosettes), including certain reserve quantities, was estimated for the two sircraft. The following aspects were discussed selection of components, installation technique, location of strain gauges, installation of the strain gauge bridges, installation time requirements, calibration, and results

STRUCTURAL IDENTIFICATION ON THE GROUND AND IN FLIGHT INCLUDING COMMAND AND STABILITY AUGMENTATION SYSTEM INTERACTION

Jun. 1976 57 p refs Partly in ENGLISH and FRENCH Presented at 42nd Struct, and Mater. Panel Meeting, Ottawa, Apr. 1978 (AGARD-R-646) Avail: NTIS HC \$4.50

Papers are presented which deal with vibration testing of aircraft and rocket vehicles, flutter analysis, particularly of the MRCA aircraft, digital techniques for flutter analysis, and interactions between aircraft structures and the command and stability augmentation system of the MRCA. For individual titles, see N76-29657 through N76-29660

M76-29657 Office National d'Etudes et de Recherches Aerospatiales, Paris (France). NEW STRUCTURAL TESTING METHODS BASED ON NON-APPROPRIATED EXCITATION

Gerard Piezzoli In AGARD Structural Identification on the Ground and in Flight Including Command and Stability Augmentation

System Interaction Jun. 1976 p 1-6 refs in FRENCH; ENGLISH summary (For availability see N76-29656 20-39)

After recalling the classical methods for determining the vibratory characteristics of an aircraft or rocket structure by a test with appropriated excitation, the paper presents two new methods that do not deliver appropriation in the Angelini method, independent excitations are located at significant points, that may number up 20 for a military aircraft with external stores. In the Dat-Meurzec method, the structure transfer functions obtained from a single, localized excitation configuration are smoothed; it is particularly convenient for the study of rockers Both methods were implemented with the computer installed in the ONERA mobile laboratory. They permit a considerable gain of time, and give results comparable to those provided by the classical mathod

N76-29658 Air Force Flight Test Center, Edwards AFB. Calif DIGITAL TIME SERIES ANALYSIS OF FLUTTER TEST

Russell W. Lenz and David A. Foreman In AGARD Structural Identification on the Ground and in Flight Including Command Jun 1976 and Stability Augmentation System Interaction p 7-24 refs (For availability see N76-29656 20-39)

A minicomputer based digital time series analysis system is used at the Air Force Flight Test Center to provide near real time estimates of modal parameters during flight flutter testing Since the test data acquired often contains noise which distorts the transfer function or autospectrum results, data smoothing algorithms are employed. These algorithms, as well as algorithms for performing multimodal analyses, have been found to be useful

when analyzing noisy aircraft data. Use of digital techniques has been buneficial both in ferms of saving time and in improving accuracy when compared with more traditional flutter testing approaches

N75-29659 Rritish Aircraft Corp., Warton (England) INFLIGHT FLUTTER IDENTIFICATION OF THE MRCA

D. K. Potter and A. Lotze (Messerschmitt-Boelkow-Blohm G.m.b.H., Munich). In AGARD. Structural Identification on the Ground and in Flight Including Command and Stability Augmentation System Interaction Jun 1976 p 25-39 refs (For availability see N76-29656 20-39)

Flutter investigations were performed prior to flight testing and during flight flutter testing of the MRCA. Because the aircraft is equipped with fast responding power control systems which could produce undestrable structural motion, flutter investigations had to be accomplished with consideration of the command and stability augmentation system (CSAS). Analysis and test results for structural mode coupling with the CSAS are demonstrated for the aircraft on ground which proved to be the condition for the lowest stability margin it was shown that there is practically no influence of CSAS on flutter behavior. The flutter speed with the lowest flutter margin was predicted for an antisymmetrical taileron mode which is modified by fuselage influences. The coupling mechanism of this mode was investigated and the effect of apex balance weight on the taileron inboard leading edge was demonstrated.

N76-29660 Messerschmitt-Bosikow-Blohm G.m.b H. Munich INTERACTION BETWEEN AIRCRAFT STRUCTURE AND COMMAND AND STABILITY AUGMENTATION SYSTEM

O. Sensburg. In AGARD. Structural Identification on the Ground and in Flight Including Command and Stability Augmentation System Interaction Jun. 1976 p 41-53 refs (For availability see N76-29658 20-39)

The multi-role combat aircraft - MRCA - has a fly-by-wire control system and automatic stabilization. The sensors for the command and stability augmentation system - CSAS - are attached to the flexible aircraft structure and may therefore pick up signals which are detrimental to the stability. This paper describes the method which was used on the MRCA to avoid CSAS- structural mode coupling effects.

N77-17527# Advisory Group for Aerospace Research and Development, Paris (France) SUMMARY OF THE DISCUSSIONS ON STRUCTURAL DESIGN TECHNOLOGY

ENERGY PROBLEMS IN A GLOBAL CONTEXT
Jacques-emile Dubois /n AGARD The 1974 AGARD Ann.
Meeting Dec. 1974 p 8-20 refs in ENGLISH and FRENCH
(For availability see N75-16977 08-44)

An analysis of the world-wide problems created by the consumption of non-renewable sources of onergy is presented. The energy system of an industrial society is described by a diagram. A correlation between the energy consumption par individual of a given country and the gross national product of the company is developed. A chart of prospective sources of energy to meet future requirements is provided. Methods for obtaining additional energy by methods which do not consume fossil fuels are explained. The characteristics of an energy system based on the use of hydrogen as the primary energy sources are defined.

N75-16879 Air Force Dept., Washington, D.C.
ENERGY-RELATED RESEARCH AND DEVELOPMENT IN
THE UNITED STATES AIR FORCE
Michael I. Yarymovych In AGARD The 1974 AGARD Ann.

Meeting Dec. 1974 p 21-30 (For availability see N75-16977 08-44)

The requirements for petroleum based energy sources by the Department of Defense of the United States are analyzed in addition to the requirements of the military forces, the logistic requirements are also examined. The impact of the energy crisis on military research and development programs to develop new energy sources for military use is examined. Methods of reducing fuel consumption by aircraft design and structural modification are proposed. The effectiveness of a campaign to reduce energy

requirements and expenditures is documented

N75-16880 Pinkel (I. Irving), Fair/iew Park, Ohio.
ALTERNATIVE FUELS FOR AVIATION
I. Irving Pinkel In AGARD The 1974 AGARD Ann. Meeting
Dec. 1974 p 31-36 (For availability see N75-16977 08-44)
CSCL 21D

The status of energy programs to provide hydrocarbon fuels from new sources is examined. Experience in the United States with non-hydrocarbon fuels for turbine powered aircraft is analyzed. The various alternate sources of hydrocarbon fuels are defined. The use of metals and metal slurries as turbine fuels is proposed. The advantages and disadvantages of liquid hydrogen as an aircraft fuel are discussed. A specific example of an aircraft operating on liquid hydrogen is described.

44 ENERGY PRODUCTION AND CONVERSION

N75-16981 National Aerospace Lab., Ameterdam (Nethorlands) IMPACT OF FUTURE FUELS ON MILITARY AERO-ENGINES

F. Jassma In AGARD The 1974 AGARD Ann. Meeting Dec 1974 p 37-46 refs (For availability see N75-16977 08-44)

The expected impact of the fossil fuel shortage on the design and operation of aircraft engines is discussed. Alternate fuels such as cryogenic fluids and synthetic fuels are proposed. Various aspects related to combustion of cryogenic and synthetic fuels are analyzed to examine the effects on seals, pumps, contamination, and engine operating procedures.

THE DISPERSION OF PROPELLANTS FROM AIRCRAFT

James A. Fay and John B. Heywood *In* AGARD The Fluid Dynamics Aspects of Air Pollution Related to Aircraft Operations Feb. 1974 p 5-16 refs (For availability see N74-28104 15-20) (Grant NGR-22-009-378) CSCL 218

Two aspects of the dispersion of pollutants from aircraft are reviewed. The first is the dispersal of aircraft exhaust emissions in the vicinity of airports; the second is the dispersal of exhaust trails in the upper atmosphere. Techniques available for modelling this dispersal and how they might be applied to the airport problem are discussed. Field studies of airport pollution are then reviewed to assess current pollutant levels around airports and the aircraft's contribution to those levels. The possibility of contrail formation from jet emissions at high altitude is then considered and the effect of uncertainties in the trial mixing processes evaluated.

AIR POLLUTION CHARACTERISTICS OF AIRCRAFT ENGINES

Robert F. Sawyer In AGARD. The Fluid Dynamics Aspects of Air Pollution Related to Alicraft Operations. Feb. 1974, p. 17-26 (For availability see N74-28104, 15-20)

Some results are presented of a survey on aircraft air pollution. The findings indicate that: (1) Aircraft are significant contributors to air pollution. (2) The engine is the primary source of aircraft air pollution. (3) Carbon monoxide and hydrocarbon emissions at low power and nitrio oxide emissions at high power are the most important immediate engine pollution problems. D.L.G.

N74-26107 Technischen Universitaet, Munich (West Germany), RESEARCH IN GERMANY ON FLUID-DYNAMICS OF AIR POLLUTION RELATED TO AIRCRAFT OPERATIONS

Franz Hindelang, J. In AGARD. The Fluid Dynamics Aspects of Air Pollution Related to Aircraft Operations. Feb. 1974 p. 27-30 (For availability see N74-26104 15-20)

An overview is presented, based on a literature survey and a questionnaire, of German research on air pollution related to alicraft operation. The literature survey revealed that while there exists an abundance of material on air pollution in general, none was found to relate to sircraft operation. The questionnaire was sent to meteorologists, serodynamicists, and aircraft companies. The answers obtained indicate a tramendous interest in the subject area with some research being conditioned but not yet at the conclusive reporting stage.

The current work being conducted in the UK in three specific areas of atmospheric poliution related to aircraft operations is summarized. The three areas are: (1) jet engine poliution in the neighborhood of airports including its generation, its reduction by proper combustion design, and its dispersal by winds; (2) smoke trails. (3) Pollution at high altitudes due to jet engine discharge, with its special problems of chemistry and dispersion.

MODELS OF THE ATMOSPHERIC AEROSOLS AND THEIR OPTICAL PROPERTIES

Eric P. Shettle and Robert W. Fenn. In AGARD. Opt. Propagation in the Atmosphere. May 1976–16 p. refs (For availability see N76-29815-20-46)

Aerosol models have been rieveloped for the boundary layer, the upper troposphere, the stratosphere, and mesosphere. In the boundary layer they describe three different environments: rural, urban and maritime. In the upper troposphere and stratosphere two different models represent spring-summer and fall-winter conditions. In the stratosphere they describe several levels of volcanic dust concentrations and the background conditions. For each model the coefficients for extinction, scattering and absorption, the angular scattering distribution and other optical parameters have been computed for wavelengths between 0.2 and 40 micrometer. The serosol models are being presented along with a discussion of their experimental basis. The optical properties of these models are being discussed and some examples of their effects on the overall atmospheric transmission properties and atmospheric contrast reduction are presented.

REMOTE AEROSOL SENSING WITH AN ASSOLUTE CALIBRATED DOUBLE PREQUENCY LIDAR

R. Reiter, W. Carnuth, M. Littfass, and N. C. Varahneya (Roorkes Univ.) In AGARD Opt. Propagation in the Atmosphere May 1976–15 p. refs (For availability see N76-29815-20-46)

A two frequency lider system, using a Q-switched ruby leser transmitter with frequency doubler and a 52 cm dia receiving telescope, for remote aerosol sensing up to more than 30 km altitude is described. The system includes electronic data acquisition and processing. Sufficient sensitivity for high altitude stratospheric measurements is provided by ten channel photon counting combined with range gating of the photomultiplier tube, and a mechanical chopper for rejection of the non-coherent ruby fluorescence. The system is now being absolutely calibrated by comparison between lidar backscatter profiles on the one hand. and theoretical backscatter functions calculated from experimental aerosol and aerological data, using Rayleigh and Mie scattering theories, on the other. The experimental data are acquired at mountain stations at 740, 1,800 and 3,000 m altitude by means of five stage impactors and of cable car probes and radiosondes. Examples of tropospheric lidar backscatter profiles, together with aerosol and serological profiles, as well as stratospheric lidar measurements are _____ inted.

T Lund and A. G. Kjelsas. In AGARD. Opt. Propagation in the Atmosphere. May 1976. 8 p. refs (For availability see N76-29815. 20-46).

A qualitative discussion pointing out some of the sources of error and fluctuations in a long cath laser differential absorption system measuring the concentration of atmospheric gaseous pollutants, is given. Except for single gas detectors using narrow optical frequency ranges, the unpredictable or unknown spread in the dispersive properties of the extinction caused by continuum absorption and scatter, is of major concern. In addition, the limitations of fast cross correlation of signals to compensate for turbulence induced fluctuation are discussed.

THE FLUID MECHANICS AND COMPUTER MODELING OF
ATMOSPHERIC TURBULENCE CAUSING OPTICAL
PROPAGATION FLUCTUATIONS

William C. Meecham In AGARD Opt. Propagation in the Atmosphere May 1976 9 p lefs (For availability see N76-29315 20-46)

Optical refractive index fluctuation are examined from the viewpoint of what is known by fluid dynamicists about atmospherio turbulence effects. Various field quantities (temperature, velocity and pressure) are written in terms of their averages and their fluctuations from those sverages. The variations of the index of refraction with the fluid variables are discussed. The cross correlations of fluid velocity, of temperature, and of velocity with temperature are presented. A new, modified discussion of the Kolmogoroff cascade theory of turbulence is presented and its consequences analyzed for their bearing upon correlation functions and energy spectra. Using this fluid mechanical information, the modeling of propagation fluctuation problems is reported using computer generated realizations of index variations, with given statistical properties.

CALGULATIONS OF POLARIZATION AND RADIANCE IN THE ATMOSPHERE

Gilbert N. Plass In AGARD Opt. Propagation in the Atmosphere May 1976 20 p. refs (For availability see N78-29815 20-46) (Grent NGR-44-001-117) CSCL 04A

Two different methods for the solution of radiative transfer problems, matrix operator and Monte Carlo, are discussed. As an example of the use of the method, results are given for the radiance and polarization of the radiation scattered from haze layers as well as from models of the real atmosphere. The variation of the radiance, polarization, and ellipticity with the aerosol amount in the real atmosphere model is presented. The Monte Carlo method is applied to the problem of calculation of the radiance and polarization of the photons in the atmosphere when there is an ocean as the lower surface. It is found that the turbidity of the ocean can be deduced from the upwelling radiance measured at some height in the atmosphere. The downwelling radiation just beneath the ocean surface is elliptically polarized at those angles where it is derived from the total internal reflection of the upwelling radiation at the ocean surface.

RADIATIVE TRANSFER IN CLOUDY ATMOSPHERES

K N. Liou In AGARD Opt Propagation in the Atmosphere 12 p refs (For availability see N76-29815 20-46) (Contract F19628-75-C-0107, Grant NSF DES-75-05216)

Band-by-band calculations have been carried out to evaluate the reflection, absorption and transmission of solar radiation by cloud layers and model cloudy atmospheres in the entire solar spectrum. The radiation transfer program is based on the discrete ordinate method with applications to inhomogeneous atmospheres. The gaseous absorption in scattering atmospheres is taken into account by means of exponential fits to the total band absorption based on laboratory measurements. Thick clouds such as numbostratus and cumulonimbus reflect 80-90% and absorb 10-20% of the solar radiation incident upon them. The reflection and absorption of a fairweather cumulus with a thickness of 0.45 km are about 68-85% and 4-9% respectively. Comparisons with aircraft observations reveal that within the uncertainties of the thickness and cloud particle characteristics theoretical computations yield higher reflection and lower absorption values for most of the water clouds. These comparisons indicate that clouds in the atmosphere are likely to consist of absorbing particles

METHODS FOR SOLVING THE EQUATION OF RADIATIVE

TRANSFER THROUGH FINITE THICKNESS LAYERS

J Lenoble In AGARD Opt. Propagation in the Atmosphera
May 1978 9 p. refs. In FRENCH, ENGLISH summary (For availability see 1176-29815 20 46)

After recalling the general problem of radiative transfer, the methods of solution for a plane parallel horizontally homogeneous atmosphere are briefly reviewed and a few numerical comparisons are shown. Then the more difficult problems of horizontal inhomogeneities and of sphericity are considered

N76-29826* Jet Propulsion Lab., Calif. Inst. of Tech. Pasadena REMOTE PROBING OF ATMOSPHERIC PARTICULATES FROM RADIATION EXTINCTION EXPERIMENTS: A REVIEW OF METHODS

Alain L. Fymat. In AGARD. Opt. Propagation in the Atmosphere May 1976 30 p. refs (For availability see N76-29815 20-46) (Contract NAS7-100) CSCL 04A

The existing methodology for reconstructing the particle size distribution and inferring the refractive index of absorbing and scattering atmospheric particulates is critically reviewed. Emphasis is placed on method capabilities and shortcomings and, wherever possible on achievable accuracy. The nature of the associated remote probing problem is analyzed with regard to the effects of the particulates on EM wave propagation in the atmosphere The parameterization of size distribution is studied within the unifying framework of Pearson's distribution curves. The inversions of extinction measurements and their ratios are considered separately, and the potentialities of each type of measurement are identified. Work lacking in each of the methods reviewed is indicated. A method of determining both the effective complex refractive index and size distribution model parameters from the same data is also presented. Lastly, determination from extinction ratio data of the complex refractive index independent of size distribution is discussed and error analyzed.

THEORETICAL STUDIES OF THE TRANSFER OF BOLAR RADIATION IN THE ATMOSPHERE

M J. Kerschgens, E. Raschke, and U. Reuter. In AGARD. Opt. Propagation in the Atmosphere May 1976 10 p refs (For availability see N76-29815-20-46)

The transfer of solar radiation in one dimensional model atmospheres has been computed for the wavelength range from 0.2 to 3.58 micrometer with an iterative solution of the radiative transfer equation. Absorption by O3, H2O, CO2, O2 and aerosols has been taken into account. The transmission in near infrared bands of CO2 and H2O is approximated by exponential series derived from spectral measurements. Various vertical distributions of H2O and serosols are considered and also two different boundaries are used: a rough ocean surface and a bright sandy desert. It is shown, for instance that as a result of the higher albedo of the sand surface, the absorption increases by 5 to 7% depending on the solar height. Aerosol layers in the lower troposphere are much more effective respective to absorption. They may alter by almost 40% the radiative heating.

N76-29828 Physics Lab. RVO-TNO, The Hague (Netherlands). THE MEASUREMENT PROGRAMME OPAQUE OF AC/243 (PANEL IV/REG.S) ON SKY AND TERRAIN RADIATION T. Baker In AGARD Opt. Propagation in the Atmosphere May 1976 10 p (For availability see N76-29815 20-46)

A measurement program on optical parameters of the atmosphere and environmental characteristics is reported. The sim of the project is to develop a data base of those parameters of the atmosphere and the environment that affect the performance of optical and electro-optical sensors during military operations. From the correlation with the meteorological data, the possibilities of forecasting the performance of the above mentioned sensors will be studied. The program consists of a minimum required set of parameters, to be measured at fixed times (every hour on the hour, local mean time) on all sites during a period of at least two years. At some of the sites a program of recommended additional measurements will be carried out during limited time

EXPERIMENTAL AND COMPUTATIONAL COMPARISON OF DIFFERENT METHODS FOR DETERMINATION OF VISUAL RANGE

W Buechtemann, H. Hipp, W. Jessen, and R. Neuwirth. In AGARD Opt Propagation in the Atmosphere May 1976 15 p. refs (For availability see N76-29815 20-46)

Three visibility meters of different type have been run simultaneously over several weeks. At the same time aerosol spectra were collected using an optical counter. The visibility readings were compared under several meteorological conditions and a Junge distribution or a modified gamma - distribution has been fitted to the experimental aerosol size distribution. Using Mie's theory and the data recorded, the readings of the instruments have been compared with the computed total extinction and the values computed based on actual instrument parameters. i.e. aspecially the angular response in the case of two scattering type instruments. A good agreement between the observational visibilities is obtained, except under particular meteorological conditions. Computed visibilities give a generally correct pradiction of the measured extinction

N76-29830 Université des Sciences et Techniques de Lille RADIATIVE TRANSFER IN A SCATTERING ASSORBING MEDIUM

Y. Fouquert and J. C. Buriez. In AGARD. Opt. Propagation in the Atmosphere May 1976 14 p refs in FRENCH; ENGLISH summary (For availability see N76-29815 20-46)

The computation of radiative transfer in a scattering and absorbing atmosphere is particularly complicated because absorption by gases and acattering by particles occur simultaneously. The most suitable method is to use the distribution of phonon optical path to disjoin absorption and scattering. The phonon optical path distribution is computed for a given scattering medium by means of Pade approximation. The solution of the transfer equation is found by any approximate or accurate method and absorption by gases is computed by means of band models. The method is presented and applied to calculate the intensity reflected by an inhomogeneous cloud

M. Kerker, P. J. McNulty, and H. Chew. In AGARD Opt. Propagation in the Atmosphere May 1978 8 p refs (For availability see N76-29815 20-46)

When inelastically scattering molecules are distributed within a small particle, they respond to the local nonuniform electromagnetic field within the particle. The outgoing inelastic field is obtained by matching at the boundary the dipole field of the emitting molecules plus an internal field with the outgoing field. In this way, it is possible to express the inelastic radiances in terms of the geometry and optical properties of the particle, of the distribution of inelestically scattering molecules within the particle, and of the molecular polarizability, for both coherent and incoherent scattering. PHYSICAL MODEL FOR STRONG OPTICAL WAVE FLUC-TUATIONS IN THE ATMOSPHERE

H. T. Yura In AGARD Opt. Propagation in the Atmosphere May 1976 24 p reft (For availability see N76-29815 20-46)

Elementary physical arguments are used to deduce the qualitative functional dependence of amplitude and phase statistics on the optical wave number, propagation distance and the parameters that describe the turbulent medium. An attempt is made to delineate the underlying physical mechanisms which produce such fluctuations and as such the derivations presented here complement the more rigorous analysis presented elsewhere. Although the discussion is limited to the basic plane- and spherical-wave amplitude and phase statistics for constant turbulence conditions, the extension to the case of inhomogeneous turbulence conditions is straightforward. Finally, the propagation of beam waves in a turbulent medium is determined from a knowledge of the propagation characteristics of spherical waves via the extended Huygens-Fresnel principle. As a result, the qualitative dependance of the characteristics of beam waves can be obtained directly from the spherical wave coherence length discussed above

LOG-NORMAL PROBABILITY DISTRIBUTION OF STRONG IRRADIANCE FLUCTUATIONS: AN ASYMPTOTIC ANALY--

Luc R. Bissonnette In AGARD Opt. Propagation in the Atmosphera May 1976 10 p refs (For availability see N76-29815

The asymptotic solutions for the first- and second-order statistical moments of the amplitude of a plane optical wave propagating in a turbulent atmosphere are derived from Maxwell's equations. These solutions show that the irradiance variance diverges to infinity if the irradiance probability distribution is everywhere log-normal. Therefore, the widely used log-normal hypothesis is incompatible with the observation of the saturation of the irradiance variance. Using the same asymptotic solutions, it is shown that the irradiance variance tends to unity if, alternately, the wave amplitude has a normal distribution in the saturation region. The latter result is much more consistent with the measured saturation levels. Finally, direct probability measurements in a simulated atmosphere tend to confirm that the actual distribution is close to normal at saturation distances.

N76-29834 Oregon Graduate Center for Study and Research.

TURBULENCE EFFECTS ON TARGET ILLUMINATION BY LASER TRANSMITTER: UNIFIED ANALYSIS AND EXPER-IMENTAL VERIFICATION

J. Richard Kerr. In AGARD. Opt. Propagation in the Atmosphere May 1976 27 p refs. Sponsored in part by DARPA and AFSC (For availability san N76-29815 20-46)

A phenomenological and analytical description is given of atmospheric turbulence effects on laser beam waves, including the improved target irradiance characteristics resulting from cancellation of turbulence induced beam wander through reciprocity tracking. The mechanisms related to the mean irradiance include diffraction, wander, and wavefront distortion (beamspreed), while irradiance fading is caused by wander, first order scintillation, and coherent feding. The phenomenological description unifies the often fragmentary and inconsistent treatment of beam wave phenomena found in the literature, and is sufficiently accurate for engineering purposes. It was shown that wander cancellation and control of the transmitter beam diameter results in substantial improvements in target illumination. The analyses are compared with experimental data for the detailed statistical and spectral characteristics of on-axis target irradi-

N76-29835 Forschungsinstitut Fuer Optik, Tuebingen (West PROPAGATION OF FOCUSED LASER BEAMS IN THE

TURBULENT ATMOSPHERE

H. Raidt In AGARD Opt Propagation in the Atmosphere May 1976 12 p refs (For availability see N76-29815 20-48)

Experimental results from investigations of instantaneous intensity distributions in focused laser beams at 0.63 micrometer and 10.6 micrometer at distances of approximately 1.3 km, 5 km and 8.6 km are presented and discussed. At 0.63 micrometer the beam pattern is broken up into several diffraction scale spots because focusing is asturated, except for weak turbulence and short propagation distance. At 10.6 micrometer the beam pattern is almost uniform, as iong as the beam dimensions are smaller than the correlation length of the amplitude.

N76-29836 Pacific Sierra Research Corp., Santa Monica, Calif. PROPAGATION OF FOCUSED TRUNCATED LASER BRAMS IN THE ATMOSPHERE

R. F. Lutomirski In AGARD Opt. Propagation in the Atmosphere May 1976 14 p refs (For availability see N76-29815 20-46)

A formula is derived for the mean intensity distribution from a finite beam in terms of the complex disturbance in the aperture and the mutual coherence function (MCF) for a spherical wave in the medium. The formula is used to examine the effects of turbulence on the long term average intensity produced by a focused, truncated Gaussian aperture distribution, it is shown that while the vacuum focal point intensity will increase as the degree of truncation degresses for a given laser output nower. the effect of turbulence limits this increase, and that the turbulence can virtually eliminate the vacuum advantage of visible over infrared wavelengths in focusing the beam at practical ranges. Transverse beam patterns and the on-exis intensity are shown for CO2 wavelength, and a criterion is established for the condition under which the turbulence prevents effective focusing. Author

A MULTIPLE SCATTERING CORRECTION FOR LIDAR SYSTEM

J.V. Winstanley and C. Wigmore. In AGARO. Opt. Propagation in the Atmosphere. May 1976. 13 p. refs (For availability see N76-29815-20-46).

Multiple scattering phenomena are treated as effective beam broadening mechanisms. At any given range the amount of beam overlap was greater in the cases of fog and smoke than in clear air. In addition, the amount of beam overlap increased as the optical density increased. A beam broadening correction factor was therefore defined as the ratio of beam overlap in poor visibility conditions to that in clear air. measured at the same range. Experimental ineasurements were made of the beam broadening factors, using a GaAc lider system. The results obtained were expressed as a graph of correction factor versus extinction coefficient for each range element, and were in fair agreement with the theoretical models of Chu and Hogg and Kunkei.

PROPAGATION OF HIGH POWER LABER BEAMS
THROUGH THE ATMOSPHERE: AN OVERVIEW
John N. Hayes In AGARD Opt Propagation in the Atmosphere

May 1976 15 p. refs (For availability see N76 29815 20.48). The major categories of the thermal blooming phenomina endountered in the propagation of high power laser thems in the open atmosphere are developed. The basic physical ideas behind each type of blooming phenomionon are discussed experimental data and theoretical formulation are briefly presunted that show the present state of knowledge. Author

N76-29844 Lincoln Lab., Mass Inst. of Tech. Lexington AN OVERVIEW OF THE LIMITATIONS ON THE TRANSMISSION OF HIGH ENERGY LASER BEAMS THROUGH THE ATMOSPHERE BY NONLINEAR EFFECTS

S Edelberg /n AGARD Opt Propagation in the Atmosphere May 1976 15 p refs Sponsored by ARPA (For availability see N76-29815 20-46)

The important nonlinear effects which limit high energy laser propagation through the atmosphere are reviewed. The two most important effects are thermal blooming (or thermal defocussing) and air breakdown within the beam. A third, less important effect is stimulated raman scattering. The possibility of transmitting laser beams through fogs, clouds or haze by boring holes through these atmospheric media with the laser beam is also reviewed The laser's waveform is considered to be a train of pulses It is shown that the waveform design and other important parameters such as range to the focal plane, aperture and focal spot size. pulse intensity, etc., can be chosen to avoid the thermal blooming of individual pulses and air breakdown. The limit on beam propagation is then caused by thermal blooming due to the cumulative heating by the pulses in the train. An added set of parameters then controls this multipulse blooming including beam slew rate, cross wind velocity, and interpulse spacing Parametric tradeoffs required to satisfactorily control thermal blooming and quantitative results for several parametric choices are sum-

Peter B. Ulrich In AGARD Opt. Propagation in the Atmosphere May 1976—19 p. refs (For availability see N76-29815-20-48).

Numerical solutions to the complex nonlinear problems of the interaction of high energy lasers with the atmosphere have played an important role in the understanding and development of this important and interesting field. Summarized are the relevant partial differential equations that apply, the kinds of numerical algorithms employed in their solution and representative results of a variety of cases of interest. Comparison with experiment made wherever possible. Other effects which impact the thermal blooming phenomena are also addressed.

N76-29846 Lincoln Lab., Mass. Inst. of Tech. Lexington THE LIMITATIONS IMPOSED BY ATMOSPHERIC BREAK-DOWN ON THE PROPAGATION OF HIGH POWER LASER BEAMS

D. E. Lencioni In AGARD Opt. Propagation in the Atmosphere May 1976 12 p. refs. Sponsored by ARPA (For availability see N76-29815 20-46)

The results of a series of experiments on laser induced air breakdown at 10.6 and 1.06 micrometers are reported. Threshold intensities for breakdown were determined for clean sir, aerosols, and single particles. The clean air threshold was found to be in good agreement with microwave breakdown theory. The presence

of serosol particles was found to lower the threshold by an amount which depended mulnly on particle size and laser pulse length. Only a slight material dependence was found with the one exception of water particles which had the least effect on threshold. The particle induced thresholds were found to scale as wavelength to the minus two power for 100 had pulse lengths. The dynamics of the particle initiated thresholds were studied. For intensities slightly above threshold the plasma grew within the beam as an axisymmetric volume surrounding the particle. At higher intensities the plasma formed as a highly absorbing thin disk which grew redially and propagated back towards the laser.

N76-29847 Lincoln Lab., Mass. Inst. of Tech., Lexington EXPERIMENTAL DETERMINATION OF SINGLE AND MULTIPLE PULSE PROPAGATION

R W. ONeil, H. Kleiman, and H. R. Zwicker. In AGARD. Opt. Propagation in the Atmosphere. May 1976–13 p. refs. Sponsored by ARPA (For availability see N76-29815-20-46).

Thermal blooming of focused single and multiple pulse lasers is considered. Experimental procedures are described to characterize the reduction in far field irradiance observed for pulses whose duration is comparable to and shorter than the acoustic transit time across a focal radius. Experimental measurements of short pulse blooming are compared with a scalar wave theoretical computer model embodying the medium hydrodynamics. Agreement with the short pulse theory is generally good. An experiment was designed to test the quantitative predictive capability of a steady state multiple pulse computer code. Blooming of a multiple pulse beam was measured as a function of absorbed energy and spatial overlap of successive pulses. Agreement between the actual measurements and those predicted by theory was very good.

COMPENSATED IMAGING

James W. Justice and Raymond P. Uitz, Jr (RADC, Griffiss AFB, N.Y.) In AGARD Opt. Propagation in the Atmosphere May 1976 17 p refs (For availability see N78-29815 20-46)

The presence of the atmosphere degrades the imaging performance of large telescopes. Optical phase distortion imposed by atmospheric turbulence causes a loss in resolution capability of from 10 to 30 times a system's theoretical performance. A compensated imaging approach is reported which allows the retrieval of low contrast information by active adaptation of the telescope system to atmospheric conditions. This is accomplished through the use of real time wavefront sensing coupled with fast response deformable optics. In practice, the wavefront entering the telescope is measured to determine its wavefront deformation (optical path length difference across the aperture) and a mirror is then deformed to the conjugate of the deformations, producing a near diffraction limited image on a sensor. Analysis of the wavefront correction capabilities has been completed.

N76-29849 Consiglio Nazional delle Ricerche, Bologna (italy) DETERMINATION OF SLANT VISUAL RANGE FROM LIDAR SIGNATURES, ANALYSIS OF SIMULATED SIGNATURES

Mario Gazzi, Vittorio Vicentini, Luca Pantani, Bruno Radicati, Leopoldo Stefanutti, and Christian Werner (DFVLR) In AGARD Opt. Propagation in the Atmosphere May 1976 19 p refs (For availability see N76-29815 20-46)

The measurement of the slant visual range by means of lidars involves two main problems: the extraction of the atmospheric extinction coefficient from the lider signature and the calculation of the slant visual range from the extinction coefficient. These problems were solved for the particular situation of a landing in low visibility conditions. An equation was obtained which allows the computation of the visual range from the extinction coefficient in every hour of the day both for extended and point sources. In order to compare the different methods for the extraction of the extinction coefficient from the Ildar signatures some atmospheric situations were simulated on a computer, and the lider equation was calculated. The simulated signatures were then processed by different methods and the results were colleted. A new procedure for the processing of lidar signatures was introduced.

N76-29850 California Univ., San Diego. COMPUTER SIMULATION OF ATMOSPHERIC TURBU-LENCE AND COMPENSATED IMAGING SYSTEMS B. L. McGlamery In AGARD Opt. Propagation in the Atmosphere May 1976 17 p refs (For availability see N76-29815 20-46)

The earth's turbulent atmosphere severely limits the resolution of conventional ground based telescopes. Methods of reducing this limitation for ground based telescopes include post detection processing in which the blurred recorded image is processed to extract information not discernable to the human visual system. and pre-detection compensation in which the wave front deformations are dynamically corrected in the optical system before the image is recorded. Computer simulations of both of these mothods are presented. The simulations demonstrate that the post detection processing method produces only moderate improvement in resolution due to signal to noise limitations while the pre-detection method gives very algorificant improvements. As a part of the simulations, techniques of generating instantaneous realizations of wave fronts deformed by atmospherio turbulence and their corresponding point spread functions are

N76-29851 Optical Science Consultants, Yorba Linda, Calif. HOW MANY PICTURES DO YOU HAVE TO TAKE TO GET A GOOD ONE?

David L Fried In AGARD Opt. Propagation in the Atmosphera May 1976 11 p refs (For availability see N76-29815 20-46)

In shore exposure imaging through turbulence, there is some probability that the image will be nearly diffraction limited because the instantaneous wave front distortion over the aperture was negligible. It is shown that the probability of obtaining a good short exposure image corresponds to a hyperspace integral in which the spatial dimensions are the independent random coefficients in an orthonormal series expansion. It is equal to the probability that a randomly chosen point in the hyperspace will lie within a hypersphere of unit radius, the points in the hyperspace being randomly chosen in accordance with the product of independent Gaussian probability distributions - one distribution for each dimension. The variances of these distributions are

directly proportional to the eigenvalues of the Karhunen-Loave equation. This hyperspace integral (involving up to several hundred dimensions) has been evaluated using Monte Carlo techniques.

REMOTE PROBING OF WINDS AND REFRACTIVE TURBU-

LENCE USING OPTICAL TECHNIQUES
S. F. Clifford In AGARTI Opt. Propagation in the Atmosphere
May 1976 10 p. refs (For availability see N76-28815 20-46)

Techniques of measuring wind and refractive turbulence by using both active and passive optical sources are considered. A passive wind sensor was developed that requires no active light source, it responds to fluctuations of light reflected from a target to determine the average grosswind. Finally, progress was made in the application of horizontal path techniques to the problem of remotely sensing wind and refractive turbulence profiles aloft from observations of stellar scintillations. The operational principles of these devices are analyzed and their performances compared to more conventional meteorological instruments.

MEASURED VISIBLE SPECTRUM PROPERTIES OF REAL ATMOSPHERES

S. Q. Duntley In AGARD Opt. Propagation in the Atmosphere May 1976 14 p. ref (For availability see N76-29815 20-46).

Measurements of the visible spectrum properties of the atmosphere which govern the apparent contrast of distant objects have been made from alreaft, spacecraft, and ground stations in various parts of the world throughout the past thirty years Samples of these data are presented and the techniques of measurement that were used are described. Examples are given to illustrate how the data can be used to predict the limiting ranges of detection, recognition, classification, and identification of any specific object by airborne, spaceborne, and ground based observers or imaging devices.

PASSIVE AND ACTIVE ATMOSPHERIC VISION

D. H. Hohn In AGARD Opt. Propagation in the Atmosphere May 1976 8 p refs (For availability see N76-29815 20-46)

The main features of a unique theory of atmospheric passive and active vision for 0,25 micrometer to 14 micrometers are discussed. The signal-to-noise ratio corresponding to the detection of the vision signal, i.e. the apparent radiance of the observation site, is used as the basic physically limiting magnitude. It establishes a general vision formula. Different noise limitations (detentor, device radiation, signal photon noise) were used to derive opecial, more applicable equations. The theoretical results were applied numerically to passive thermal vision. The optimization of optoelectronic vision systems was considered by approaching signal limited photon noise conditions in contradiction to blip conditions, and by using reduced wavelength bands for atmospheric vision. Finally, the problem of defining and measuring characteristic lengths comparable to the visual range 5 was considered.

N76-29855 Physics Lab. RVO-TNO, The Hague (Netherlands). DECREASE OF CONTRAST IN THE ATMOSPHERE: STATISTICAL PRESENTATION OF THE RESULTS OF DAYTIME AND NIGHT-TIME MEASUREMENTS

J. VanSchle and J. Rogge (Roy. Mil. Acad., Brada, Netherlands) In AGARD Opt. Propagation in the Atmosphere May 1976 16 p refs (For availability see N76-29815 20-46)

An outline is given of the model in which the decrease of contrast in the atmosphere in the visible region is described with two parameters: the extinction coefficient and the luminance of the atmosphere; also the distance over which the initial contrast is halved, is introduced. The results of a number of measurements of these parameters, both at day and at night, are presented in the form of several histograms. Some comments concerning the results of the various measurements are given.

N76-29856 Norwegian Defence Research Establishment, Kjeller. BENDING OF RAYS OF LIGHT ABOVE THE SEA BUR-FACE

P. A. Stokseth and A. Nordbryhn In AGARD Opt. Propagation in the Atmosphere May 1976 14 p refs (For availability see N76-29815 20-46)

A temperature difference between the sea and the air above it sets up a stable vertical air temperature gradient in the first few meters above the sea surface. This temperature inhomogeneity causes a similar refractive index gradient. Rays of light passing through this optical inhomogeneous medium are bent, and imaging of objects through this medium may be subject to strong distortion. Such image distortion has been investigated, theoretically and experimentally. The main experimental results were obtained by taking pictures of a suitable test object with a photographic camera and a telephoto lens at 8.2 km range just above the sea surface. From these pictures typical forms and magnitudes of the distortion were found. A mathematical model tracing rays of light through a vertically varying optical medium was used to predict image distortions. The theoretical results have been compared with the experimental results, and good similarity has been found.

ATMOSPHERIC LIMITATIONS OF ACTIVE AND PASSIVE NIGHT VISION SYSTEMS

E.G. D. Youngs. In AGARD. Opt. Propagation in the Atmosphere May 1976. 7 p. refs. (For availability see: N76-29815. 20-46).

The ways in which the earth's atmosphere effect the image quality of night vision devices are discussed, and of particular interest here is the effect on apparent contrast. Atmospheric problems are considered that are associated with the use of supplementary illumination. Continuously emitting searchlights are briefly outlined, and techniques associated with pulsed illuminators are considered. A summary is given of a basic mathematical model for such a system.

USING LIDAR FOR MEASURING VISIBILITY
James F. Ruger In AGARD Opt. Propagation in the Atmosphere

May 1976 8 p. refs (For availability see N76-29815 20-46)

The performance of slant visibility equipment and the data processing techniques used, are described. Special attention is given to the correlation data which compares the accuracy of the slant visibility system to that of a recognized transmissometer. Approximately 800 slant visibility readings were compared with the transmissometer visibility data at three different airports in order to obtain the correlation function. The results show that in slant visibility readings, although consistently higher than the transmissometer visibility reading, the factor is always approximately two. Therefore the correlation factor is a constant, and the visibility data plots of the two systems lie exactly parallel to one another.

H.-E Hoffmann In AGARD Opt. Propagation in the Atmosphere May 1976 16 p refs (For availability see N76-29815 20-46)

During some preliminary visibility sin-to-ground and ground-to-air tests in autumn 1974, the maximum detection range and the maximum recognition range were determined A Leopard tank, a 1.5 t military truck and a special test board were observed from air to ground. The experiments took place only at standard visibilities between 36 and 57 km - the maximum detection range ground-to-air was between 8 and 12 km larger than the maximum detection range air-to-ground. The maximum recognition range air-to-ground was up to 2 km smaller than the maximum detection range. The maximum detection range for observations of a special test board was smaller than that for observations of the 1.5 t military truck. The maximum recognition ranges, however, determined at observations of the test board and of the 1.5 t military truck did not differentiate significantly from each other.

EVALUATION OF ROLL AXIS TRACKING AS AN INDICA-TOR OF VESTIBULAR/SOMATO SENSORY FUNCTION

A. M. Junker and C. R. Replogle In AGARD Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircraw Feb. 1975 B p refs (For availability see N75-23084 14-51)

To learn more about the effects of vestibular/somato sensory information upon visual motor control, a roll axis tracking simulator was developed. A description of this simulator, including the ability to run with and without motion dues, is given. Large amplitude roll angle motion dues were used. The effects of various plant dynamics, relating to plant complexity on tracking performance, are discussed. For a particular set of plant dynamics requiring a considerable amount of lead compensation, it is shown that subjects perform significantly better with the presence of motion cues. It has been suggested that primarily vestibular system contributions allow motion cues to aid pilot performance.

THE EFFECTS OF PURE YONE HEARING LOSSES ON AVIATORS' SENTENCE INTELLIGIBILITY IN QUIET AND IN AIRCRAFT NOISE

G. R. Froelich In AGARD Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircrew 1975 4 p (For availability see N75-23084 14-51)

Pure tone audiometry remains the basis for the acceptance of applicants as well as the annual follow-ups of rated pilots. Speech audiometry in quiet is very afficient for the essessment of disability for compensation and the selection of hearing aids, but not for decisions on deafened alicrew. Present audiometric standards for rated aircrew make sure that aviators with hearing losses admitted by standards have no difficulties with inflight voice communication. The decision on the disposal of experienced but desfened sircrew should be based on the discrimination of connected speech in the presence of a background aircraft

ASSESSING AN AVIATOR'S ABILITY TO HEAR SPEECH IN HIS OPERATIONAL ENVIRONMENT
Carl E. Williams, James D. Mosko, and James W. Greene In

AGARD Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircrew Feb. 1975 10 p refs (For availability see N75-23084 14-51)

The use of multiple word test Items is analyzed whether it influences the intelligibility function of test words relative to their presentation as single word test items and whether such items provide a sensitive measure of an individual's ability to hear speech in aircraft acoustical environments. High quality tape recordings were constructed of single, double, and triple word test items from six monosyllabic word lists of the Modified Rhyme Test (MRT), a multiple choice intelligibility test. The test words were incorporated in a carrier phrase somewhat analogous to typical aircraft radio messages. The recorded lists were mixed with shaped noise and played back to a group of listeners at three signal-to-noise ratios. At the two best signal-to-noise ratios (+4 db and 0 db), there was little difference in overall listener performance for the single, double, and triple word test items

Robert T. Camp, Jr., Ben T. Mozo, and James H. Patterson In AGARD Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircraw Feb. 1975 6 p (For availability see N75-23084 14-51)

Military voice communication systems have two undestrable characteristics: (1) they have excessive distortion that causes low intelligibility; and (2) they emit excessive noise which constitutes an acoustic hazard to military personnel. A prototype voice communication system is developed that includes a new generation noise cancelling microphone. Results of a test are presented to show that near field linearity and improved noise cancelling characteristics are the desired characteristics of future noise cancelling microphones.

OBJECTIVE ELECTROPHYSIOLOGICAL MEASUREMENTS OF EAR CHARACTERISTICS, INTELLIGIBILITY OF VOWELS AND JUDGEMENT OF THE STAGE OF ATTENTION
Manfred Spreng In AGARD Med. Requirements and Exem.

Procedures in Relation to the Tasks of Today's Aircrew 1975 10 p refs (For availability see N75-23084 14-51)

The influence of short time annoying noise upon evoked human responses can be demonstrated if the noise reaches intensities around 70 db. Ear characteristics measured show objectively the behavior of the individual ear in the range above the increased thresholds. Based upon their course compensating hearing side can be adapted which do not only amplify in a variable degree but also may show even a range of attenuation with increasing sound pressure levels in some special cases of recruitment. Using computer generated vowels as exactly triggered stimuli evoked responses have been recorded with a 16 to 37% increase compared with speech noise stimulation of equal intensity near threshold. First trials are reported to select the single responses corresponding to the FFT-EEG spectra, thus, overcoming the influence of different stages of attention. By this means new date may be gathered concerning the change of evoked potentials from change of attention doing additional tasks, having multisensory input or succumbing sedation. Author

AIR-TO-AIR VISUAL TARGET ACQUISITION

James E. Goodson In AGARD Med. Requirements and Exam.

Procedures in Relation to the Tasks of Today's Aircrew Feb.

1976 9 p refs (For svallability see N75-23084 14-51)

A most critical element of tactical advantage in the air combat anvironment is the early visual acquisition and continued visual reacking of airborne targets. Little data are available which relate specific visual functions or tests to air-to-air performance ability. Initial visual acquisition of airborne targets usually occurs at distances far less than calculated visibility ranges. Further, many targets go undetected even though they pass well within the acquisition range. There appears to be great variability among aviation personnel in visual acquisition performance. However, potential procedures for either selecting or training personnel for this special ability have not been validated against inflight performance criteria.

MICROSTRABISMUS IN FLYING PERSONNEL (DIAGNOSIS AND DISPOSITION)

Thomas J. Tredici In AGARO Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircrew Fab. 1975 10 p. refs (For availability see N75-23084 14-51)

It is considered of paramount importance for the aviator to have the ability to accurately perceive depth and judge distances. One of the important elements contributing to his depth perception is stereopsis. The United States Air Force (USAF) depth perception tests are in reality tests of stereopsis. Examiners are aware that a number of trained aviators slews have difficulties in pessing, these stereoscopic tests. In the pest those who failed these tests but had straight eyes and normal visual acuity were thought to have idiopathic partial lack of stereosculty, most likely on a central basis. Recently developed subtle diagnostic motility techniques have revealed that many of these airmen in reality

have a small degree of strabismus (crossed eyes). Presently, this condition is known as microstrabismus or microtropia.

LINEAR ACCELERATION PERCEPTION THRESHOLD
DETERMINATION WITH THE USE OF A PARALLELSWING

A. J. Greven, W. J. Oosterveld, and W. J. A. C. Rademakers. In AGARD. Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircrew. Feb. 1975. 4 p. refs. (For availability see N75-23084.14-51)

The perception of linear acceleration in humans is discussed. The parallel swing -as a tool to collect data on the functioning of the otolithic system- is described. In twelve human subjects experiments were conducted with the parallel swing in order to determine the threshold of porception for movements of this swing. The effect of different body positions on this threshold was also determined. In another series of experiments the amplitude of the sinusoidal compensatory eye movements was investigated when the swing was oscillating with an amplitude of 12.5 cm, as well as with an amplitude of 25 cm. COMPUTER MEASUREMENT OF COMPLEX PERFORM-

Richard S Gibson In AGARD Med Requirements and Exam Procedures in Relation to the Tasks of Today's Aircrew Mer 1975 7 p. refs (For availability see N75-24297-15-51)

A series of computer controlled performance measurement tests using response latency measures were developed. Three types of performance tasks were used in these tests an experimenter paced complex discrimination task, a subject-paced complex discommanda task and an experimenter baced stress task Each task is capable of boing presented separately or in conjunction with other tasks. This quality permits the assessment of performance changes as the test environment is changed from a simple single task situation to an increasingly complex multiple task situation. The results indicate that response times under complex conditions are much longer than under simpler task conditions. Task interactions and the need to divide attention presidy increase the time required to respond to any test situation. Some individuals appear to be more able to cope with time-shared conditions than others. In general, the data indicate that much of the traditional human performance data may grossly overestimate performance levels obtainable under real-world conditions.

N75-24301 Organization for Health Research, TNO. Amsterdam (Natherlands). Lab for Ergonomic Psychology. CHANGES IN VISUAL EVOKED RESPONSE BY NON-VISUAL TASK PROCESSING

J. L. Blom. In AGARD Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircrew. Mar. 1975. 11 p. refs (For availability see N75-24297. 15-51).

The influence of an auditory binary choice task on the visual evokud response (VER) in man is analyzed. The separation of task and test stimulus and the processing techniques used enabled the demonstration of a significant difference between task and resting conditions, especially in the amplitude levels of wave IV. These observations, together with data from literature form the basis of a neurophysiological hypothesis advanced to explain the responsable mechanisms. It is postulated that, in the waking state, the reticular formation can only be in two states designated resting and busy, which are responsible for the cortical processing of information. The busy state occurs when information is processed and is maintained by cortico-reticular activity during this state. If this activity has been maintained during a certain period of time, return to the resting state is delayed, changing the VER in the period immediately following mental activity

PULSE WAVE VELOCITY OVER THE VASCULAR WALL AS A MEANS FOR DISTINGUISHING BETWEEN DIFFERENT PSYCHOPHYSIOLOGICAL REACTION PATTERNS TO A MENTAL TASK

C.H.J. M. Opmeer. In AGARD. Med. Requirements and Exam. Procedures in Relation to the Tasks of Today's Aircrew. Mar. 1975. 7 p. refs (For availability see N75-24297.15-51).

The influence of a quentitative task of a predominantly mental nature on pulse wave valicity (PWV) was invostigated. The time which the pulse wave (caused by the pumpling action of the heart) needed to travel along the vascular wall (from heart to right ear lobe) generally decreased (i.e. PWV increased) during a 75 choices per min - tack it seems possible to distinguish two groups, those subjects showing a decreased PWV (supposed to indicate arterial vasconstriction), and those showing an increased PWV (supposed to be caused by vascidilation). The continuous PWV-time series appears to be quite irregular (mean SD 16 ms) A Fourier analysis performed on these data indicates that the observed increase in the number of oscillations during a heavy task is due to an influence of augmented respiratory rule during this task.

CATECHOLAMINE EXCRETION FROM AIR CADETS

G Paolucci and G. Blundo in AGARD Med. Requirements and Exam. Procedures in Relation to the Tasks of Toulay's Aircraw Mar. 1975. 3 p. refs. (For availability see N75-24297. 15-51).

As every stress can produce rise on catecholamine rate (as adrenal gland response), these substances in aviators during training were analyzed, in order to establish whether the flight could have some influence in their output. The assessment of

the data obtained results in the conclusion that, in air cadets, first flying missions act as a stress, since the catecholamine oxiciation increases 4 times in comparison with basic values, collected during nonflying duty.

FLIGHT FITNESS AND PSYCHO-PHYSIOLOGICAL BEHAV-IOR OF APPLICANT PILOTS IN THE FIRST FLIGHT MISSIONS

Cesare A Remacci and Paolo Rote In AGARD Med Requirements and Exam Procedures in Relation to the Tasks of Today's Aircrew Mar 1975 8 p. refs (For availability see N75-24297 15.51)

The psycho-physiological behavior of 73 applicant pilots was studied during the flights of a basic training course. On ground and during the 1st. 7th. and 15th mission, the trainess carried out srithmetic calculation consisting of progressiv's subtractions, and tracked a given outline. In the same missions, in a few trainess, heart rate was continuously recorded with magnetic tape electrocardiograph, and related to flight tasks. The data obtained are discussed with respect to the results of flight final tests, preliminary psychological selection, and previous flight experiences in order to evaluate their importance to flight fitness assessment.

N78-24305 Royal Air Force Inst. of Aviation Medicine. Farnborough (England). SOME FAST ANALYTICAL TECHNIQUES FOR THE EEQ.

G H Byford In AGARD Med Requirements and Exam Procedures in Relation to the Tasks of Today's Aircrew Mar. 1975 10 p refs (For availability see N75-24297 15-51)

Three fast single or multichannel techniques were developed and investigated. The shape and size of an electrical signal may be described by means of the amplitude probability density. This statistical characteristic can be calculated on-line for several channels simultaneously, and techniques are available to detect significant differences between one epoch and another of the same channel, or between epochs from different channels. Using a small analogue computer, the signal from a single channel may be divided into 5 frequency bands approximating the accepted physiological definitions; for each, the time course of the integral of signal variance is then plotted automatically at up to 16 times real-time, and the slopes of the curves used to obtain numerical indices of change in eeg activity. It is intuitively satisfactory to describe the eeg in terms of amplitude, frequency and time, but no simple graph will display the in-terrelationship between these 3 variables. The power spectial density describes the relationship between frequency and amplitude in one epoch, successive spectra can be organized so as to produce a 3 dimensional display, and a technique based on the fast Fourier transform was devised which will satisfactorily decrease the spectral density computer time, by a factor of up to 100. In order to carry out these calculations with adequate speed, a hybrid computing system, was developed which may be controlled either from an on-line experiment or from an index placed on one track of an analog FM recording; results are presented as graphs or printed tables.

IMPACT OF MULTIVARIATE ANALYSIS ON THE AVIATION SELECTION AND CLASSIFICATION PROCESS

Norman E Lans and Resalte K Ambler In AGARD Med Requirements and Exam Procedures in Relation to the Tasks of Today's Aircrew Mar 1975 7 p refs (For availability see N75-24297 15-51)

Continuous quality control which has evolved from the massive use of multivariate statistical techniques made possible by modern computer technology is described along with the selection and classification process from the first coarse screen at widely separated procurement points through the first fleet assignment. Emphasis is on the role of multivariate analysis in the development of statistical forecasts of performance for various points in time within each training option. Among the multivariate techniques that were employed are factor analysis, multiple group discriminant function, and multiple regression analysis. Multiple regression analysis is the most productive and is the principal technique currently used to produce the many series of successive prediction. equations which combine quantitative and qualitative data from numerous sources. Comparisons of the multiple regression. prediction model with other techniques are made and refinements developed in use of this technique are discussed. These refinements are concerned with minimizing the impact of sampling error on validity, the handling of potential suppressors, and the development of decision rules for variable selection. These decision rules encompass the practical demands of the training situation as well as the mathematical properties of the potential predictors.

PSYCHIC HEALTH: A QUANTITE NEGLIGEABLE IN FLYING FITNESS EXAMINATIONS

H. P. Goerres In AGARD Med. Requirements and Exam.
Procedures in Relation to the Tasks of Today's Aircrew Mar.
1975 6 p refs (For availability see N75-24297 15-51)

After a comparative enalysis of possibilities and results of aptitude diagnoses so far applied to applicants by aviation psychologists, experiences gained in routine and psychological follow-up examinations are reported. Various suggestions for the accomplishment of periodic psychologic examinations in the German Air Force are offered and discussed, emphasizing practicability and effectiveness of the different possibilities in detail. It is shown that examinations of this kind could be conducted by the German Air Force without additional expenditures in personnel, provided certain organizational prerequisites are met.

SIXTEEN YEARS EXPERIENCE IN MILITARY AVIATION PSYCHIATRY AND NEUROLOGY

P. J. OConnor In AGARD Med Requirements and Exam.
Procedures in Relation to the Tasks of Today's Aircrew Mar
1975 3 p. refs (For availability see N75-24297 15-51)

The wastage of aircrew due to psychiatric causes is discussed. One approach to psychiatric selection is to forecast how a cadet will withstand the stress of flying on the evidence of his previous life history, the approach was investigated. Two ways of tackling psychiatric wastage are found to be the physiological measurement of the cadet's ability to adapt to stress, and the acceptance of the fact that the only test for fitness for flying is the flying itself. It is found that neurological wastage of aircrew a much smaller than psychiatric wastage, and that routine electroencephalography may futher reduce neurological wastage by identifying those likely to develop epilepsy.

AIRCREW ASSESSMENT OF THE VIBRATION ENVIRON-MENT IN HELICOPTERS

B. H. Rance and J. W. Chappelow In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 7 p. refs (For availability see N75-27685 16-51)

A survey of military helicopter crews was carried out to determine the scope and nature of problems due to vibration. Three hundred questionnaires were completed. The chief consequences of vibration were discomfort and difficulty in reading displays. The occurrence of these effects was associated with significant increases in reported fatigue. The major effects were, mainly confined to the larger aircraft. Most of the reports from Royal Navy helicopters were associated with hovering or transition to or from the hover; turbulence was found to increase the number of reports of vibration effects. Loading of the sircraft was not found to cause any increase in the number of reports.

HUMAN EXPOSURE TO WHOLE-BODY VIBRATION IN MILITARY VEHICLES AND EVALUATION BY APPLICATION OF 180/DIS 2631

Heiririch Dupuls In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 7 p refs (For availability see N75-27685 18-51)

The vibration strain of soldiers and test drivers in military vehicles concerns mainly those reactions which, by the way of influencing the sensation and motoric coordination, can decrease the human performance when operating vehicles and carrying out military tasks. So especially visual sensation will be influenced by vibration stress. Furthermore, vibration at high amplitude in certain frequency ranges may lead to injuries to health. Results of vibration measurements in 13 wheeled vehicles, 3 tanks and 2 ambulances show that the vibration stress under certain conditions may be very high. By the use of national and international standards the measured vibration stress is evaluated. As consequences of these results technical improvements and daily exposure time limits are proposed.

N75-27688 Surface Effects Ship Project Office, Bethesda, Md. CREW PERFORMANCE REQUIREMENTS IN THE VIBRA-TION ENVIRONMENTS OF SURFACE EFFECT SHIPS

Aifred Skolnick In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 22 p refs (For availability see N75-27685 18-51)

Basic requirements and habitability standards are studied for designing surface effect ships employing a self generated outhion of air for lift support with vertical motion centering in the 0.2 to 3.0 Hz region. Emphasis is placed on vibratory loads and crew performance. Using empirical data from 100-ton testcraft and motion predictions from a 2000-ton SES math model, a simulated pilot house is stimulated to portray ship response characteristics at various speeds in diverse ses states. Results of these motion simulations and selected critical crew tasks conducted during the tests for up to four hour intervals are discussed. Author

THE TRANSMISSION OF ANGULAR ACCELERATION TO THE HEAD IN THE SEATED HUMAN SUBJECT G. R. Barnes and B. H. Rance In AGARD Vibration and Combined

Stresses in Advan. Systems Mar. 1975 7 p refs (For availability see N75-27685 18-51)

Sinusoidal angular oscillation in yaw of seated human subjects, both restrained and unrestrained, has demonstrated that responses of significant amplitude may be elicited in all three head exes. In the unrestrained condition, the torso appeared to absorb the input acceleration, the response of the head in the yew axis exhibiting very rapid attenuation and large phase lags at frequencies above 4 Hz. In the restrained condition, the transmission to the yaw axis of the head was much less severely attenuated with smaller phase lags above 4 Hz. The yaw responses In the unrestrained condition exhibited a resonant peak at 2. Hz. In both experimental conditions there was a significant response in both the roll and pitch axes of the head. The response in pitch exhibited significant 2nd hermonic components which were manifested as a frequency doubling effect between 1 and

THE EFFECT OF THE INDIVIDUAL AND COMBINED STRESSES OF VIBRATION AND SUSTAINED G ON PILOT PERFORMANCE

A. G. Piranian In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 13 p refs (For availability see N75-27685 18-51)

The human centrifuge was used to evaluate the relative influences of sustained normal accelerations, combined vertical and lateral buffet loads, and basic alroraft flying qualities on air-to-air tracking performance in air combat maneuvering flight. Performing the simulation in an actual F-4B cockpit, 11 pilots were tasked with tracking a moving target with a fixed reticle sight presented in visual display. Sustained accelerations from 1.3 to 5.0 g/s, buffet intensity levels from buffet free to + or -.6 g, and lateral directional flying qualities were varied in-dependently in several combinations to assess their individual and combined influences on tracking precision. Results show that for the buffet frequency used (10 cps), intensities up to \pm or - .5 g have negligible effects on performance. Sustained accelerations up to 5.0 g's have appreciable effects, degrading tracking by 10 mile over the 1.0 g level. Flying qualities' influences were substantial, and greater than those of either buffet or addeleration. Decreased dutch roll frequency and/or damping. adverse alleron yaw, and proverse alleron yaw were seen to have degrading effects on performance.

Walter M. Braunohler In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 7 p. refs (For availability see N75-27685 18-51)

No significant change occurs in bone mineral density after short term helicopter flying. However, the impact conditions of basic physical training induce 10% demineralization of the distal ulns. It is our impression that this is a transient phenomenon. Long term follow-up of helicopter pilots flying 6.5 hours/week over two years reveals no evidence of musculoskeletal strain; however, there appears to be a trend towards demineralization of the distal radius. Continued monitoring of this population group is recommended to determine when pathological changes may be expected to occur.

THE RESPIRATORY AND METABOLIC EFFECTS OF CONSTANT AMPLITUDE WHOLE-BODY VIBRATION IN MAN

G. R. Sharp, G. A. Patrick, and W. R. Withey In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 6 p refs (For availability see N75-27685 18-51)

Nine human subjects were exposed to constant amplitude whole body. G sub z vibration, for 10 minutes, at frequencies of 2, 4, 6, 8 and 10 Hz. It was found that at 2 and 4 Hz pulmonary ventilation, oxygen uptake, and tidal carbon dioxide tension and heart rate were unchanged. At frequencies of 6, 8 and 10 Hz, however, there was an increase in pulmonary ventilation and in oxygen uptake. Pulmonary ventilation was increased in excess of the oxygen uptake, resulting in hyperventilation. There were no qualitative or quantitative differences in values of pulmonary ventilation or oxygen uptake between subjects when unrestrained and when fully restrained on the vibrator. Most subjects experienced discomfort or prin during exposure to frequencies of 8, 8 and 10 Hz. It is considered that this pain induced the observed hyperventilation. The increase in oxygen uptake is thought to be related to the tensing of musculature.

A STUDY OF VIBRATION, PILOT VISION AND HELICOPTER ACCIDENTS

Michael J. Griffin In AGARD Vibration and Combined Stresses in Advan. Systems Mar 1975 16 p refs (For availability see N75-27686 18-51)

A series of experiments has been conducted to investigate the hypothesis that the occurrence of helicopters flying into wires is associated with vibration having a detrimental effect on pilot visual adulty. The research commenced with an investigation of the evidence for the problem by surveying the incidence of wire strikes and determining the conditions in which they occur. The second study measured pilot visual acuity during flight in two different helicopter types it was concluded that under normal conditions the loss of visual acuity in these two helicopters was unlikely to be a major cause of wire strikes. The third investigation resulted in the detailed specification of the vibration experienced in the Scout AH Mk 1 helicoptes. Particular emphasis was placed on the changes in vibration with the various flight conditions and the differences between pilots and between aircraft of the same type. The final series of experiments were designed to determine the minimum levels of vibration which would affect visual soulty

MECHANISMS OF VIBRATION EFFECTS ON AIRCREW PERFORMANCE

Richard W. Shoenberger In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 9 p rafs (For availability see N75-27685 18-51)

The effects of vibration on a variety of human performance tasks are reviewed. Research is categorized with respect to the predominant performance requirements of the tasks investigated, and results are evaluated in order to determine which aspects of task performance (sensory input, central processing, and motor output) are affected by vibration interference. This procedure reveals that the vast majority of vibration effects occur for tasks which require fine sensory discrimination or precise motor response, or both; only a very few studies show effects which can be attributed to interference with intellectual or cognitive functions. On the basis of logical analyses of differential vibration effects on various types of tasks it is suggested that the predominant mechanism for vibration performance effects is direct mechanical interference with functions occurring in the input and output stages of operator performance tasks. Vibration effects on tasks which are primarily intellectual in nature and have minimal sensorimotor requirements are discussed in relation to generalized stress mechanisms. Recent research is described in which analytical decomposition of reaction time measures made it possible to definitively isolate vibration effects on peripheral and central performance functions within a single task.

N78-27701 Dayton Univ. Research Inst., Ohio. PERFORMANCE AND PHYSIOLOGICAL EFFECTS OF COMBINED STRESS INCLUDING VIBRATION

J. C. Guignerd In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 6 p refs (For availability see N75-27685 18-51)

Whole body vibration affects human task performance by two main mechanisms: peripherally by mechanical interference at the point of contact between the man and his task; and centrally, by burdening the brain with irrelevant sensory information. In the latter regard, the action of vibration is in some ways akin to that of noise. Any particular effect of vibration on performance depends on many factors, including the physical characteristics of the vibration, the nature of the task and the skill and motivation of the performer, time, and the presence of other stressful agents or circumstances. Unfortunately, our ignorance of the psychophysiological mechanisms by which vibration degrades particular kinds of task performance is still profound, and our knowledge for the most part qualitative in nature. That is mainly because much laboratory based research into the psychophysiological actions of vibration suffers from the lack of an appropriate standardized methodology and of complete and proper measurements of the vibratory forces affecting the man at the time when his performance is being

EFFECTS OF DURATION OF VERTICAL VIBRATION
BEYOND THE PROPOSED ISO "FATIGUE-DECREASED
PROFICIENCY" TIME, ON THE PERFORMANCE OF
VARIOUS TASKS

R. T. Wilkinson and R. Gray (RAE, Farnborough, England) In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 5 p. refs (For availability see N75-27885 18-51)

Six subjects carried out four 3-hour sessions of performance tasks, two with continuous 5 Hz. 1.2 m/s squared rms vertical vibration and two under static conditions. There was no general support for a prediction from the proposed ISO curves of fatigue-decreased proficiency (FDP) that vibration can lower proficiency as a function of duration of exposure. However, vibration associated with a 1-hour vigilance task and knowledge of results decreased proficiency towards the end of the 3-hour work period.

PERIPHERAL VISION ARTIFICIAL HORIZON DISPLAY

R. Malcolm, K. E. Money, and P. Anderson. *In Its* Vibration and Combined Stresses in Advan. Systems. Mar. 1975. 3 p. ref (For availability see N75-27685.18-51).

The artificial horizon instrument currently used in aircraft suffers from two shortcomings; the pilot cennot obtain continuous information from it, since he must also look at other instruments

and second, during episodes of heavy vibration, turbulence or disorientation, a small instrument becomes extremely difficult to read. This paper describes a device which projects a line or bar of light from beside the pilot's head forward onto the instrument panel. The line is approximately one to four inches wide and subtands 160 - 170 deg of arc from the pilot's head, so that it extends well into his peripheral vision. The light source is driven by servomotors which are controlled from the aircraft's inertial gyros, such that the bar of light seen by the pilot duplicates the pitch and roll motions of the real horizon outside the cockpit. The advantages of this display are: visibility during turbulence and vibration, visibility while looking at other instruments, and reduction of the pilot's workload by making use of the neural programming which naturally orients us with the horizon.

A REVIEW OF BIOMECHANICAL MODELS FOR THE

A REVIEW OF BIOMECHANICAL MODELS FOR THE EVALUATION OF VIBRATION STRESS

Wolfgang Lange In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 8 p. refs (For availability see N75-27685 18-51)

Physical resonances of the human body or of its parts under vibration correlate with subjective responses. Biodynamic models can be calculated from data of vibration investigations. Several such models are discussed. The models differ in their degrees of freedom, in their mass, elasticity and damper elements, and in the way these elements are coupled. A further important parameter is the linearity or nonlinearity of the model. For the evaluation of vibratory stress it is necessary to establish physiological and/or psychological criteris which correlate with biomechanical responses that can be simulated by models. Several methods for evaluating vibration stress are discussed and compared.

AN ELEMENTARY PSYCHOPHYSICAL MODEL TO PREDICT RIDE COMFORT IN THE COMBINED STRESS OF MULTIPLE DEGREES OF FREEDOM

Ralph W. Stone, Jr. In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 7 p. refs (For availability see N75-27685 18-51)

The quality of sirplane rides probably will become increasingly important to passengers, particularly in terminal area operations and on short haul trips. The development of models to predict ride comfort is considered. An elementary model concapt is presented herein and compared with subjective ride comfort response ratings measured on actual scheduled sirline flights and simulated flights.

MODELS OF THE CARDIOVASCULAR SYSTEM UNDER
WHOLE BODY VIBRATION STRESS

Charles F. Knapp In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 13 p refs (For availability see N75-27685 18-51)

Five major mechanisms can be listed as the main factors responsible for producing alterations in the circulatory system exposed to vibration. The mechanisms important for vibration stress of a given waveform, frequency, displacement, acceleration, transmitted force, axis, and duration are: (1) reaction of the fluid and vessel system; (2) reaction of large body organ systems and the musculoskeletal system; (3) reaction of the mechanoreceptors; (4) reaction of the hormonal metabolic and hematological systems; and (5) reaction modification through the central nervous system and the psychophysiological pathways. Analytical efforts are reviewed as they relate to the five mechanisms listed above and current efforts in modeling the hydrodynamic aspects of the cardiovascular system are discussed in order to estimate its relative contribution to the total changes in arterial pressures and flows measured in animals exposed to whole body sinusoidal vibration.

N75-27707 Systems Technology, Inc., Hawthorne, Calif. EVALUATING BIODYNAMIC INTERPERENCE WITH OPERATIONAL CREWS Henry R. Jax and R. Wade Allen In AGARD Vibration and Combined Stresses in Advan. Systems Mar. 1975 18 p refs

(For availability see N75-27685 18-51)
A review is made of operational situations in which blodynamic interference with aircrews is a problem, and it is shown that there is a large contrast between the information needed to

evaluate these problems in operational situations versus that available from existing laboratory research. A structure and means for extrapolating the large and growing empirical data base is discussed. Some progress in work along these lines is presented, including: Systems performance models for interrelating the many variables; refined biomachanical models for analyzing vibration feedthrough to controls in closed loop manual tasks; and procedures for including habitability or ride ratings in the overall avaluations

THE ISO GUIDE FOR THE EVALUATION OF HUMAN WHOLE BODY VIBRATION EXPOSURE

G Bobbert In its Vibration and Combined Stresses in Advan-Systems Mar. 1975 6 p. refs (For availability see N75-27685

It exists a demand for regulations to evaluate the vibration exposure of human beings. Although the knowledge of the human reaction is not sufficient for all cases of vibration exposure, experts from ten countries discussed a standard which gives a guide for the evaluation. As this standard is agreed by the ISO-Council and it is now going to be printed, the background of this standard and the most important details are reported. Author

VERTICAL VIBRATION, 0.1 TO 1.0 Hz
Geoff Allen In AGARD Vibration and Combined Stresses in

Advan. Systems Mar. 1975 11 p refs (For availability see N75-27685 18-51)

The need for design standards for civil and military vahigles to cover human reaction to vibration below 1 Hz is outlined. Limits are proposed against two criteria: the first, to prevent severe discomfort merges at 1 Hz with the DIS2631 exposure limit; the second, to prevent reduced comfort merges at 1 Hz with the DIS2631 reduced comfort boundary. Because of lack of information, limits have been given for 25 minute and 8 hour durations only, and it has not been possible to suggest values for the preservation of working efficiency. The information on which the proposals are based is outlined, namely some twenty laboratory and field investigations and critical reviews, yielding about fifty data points. Considering the approximate nature of some of the information it is relatively consistent, and reinforces previous assertions that the critical frequency range for motion sickness is below 0.5 Hz.

RIDE QUALITY OF CREW MANNED MILITARY AIRCRAFT

Stanley H. Brumaghim In AGARD Vibration and Combined Stresses in Advan. Systems Mer 1975 7 p. refs (For availability see N75-27685 18-51)

Ride quality criteria are compared in terms of both short term and extended term crew performance decrement thresholds. Flight test data are included which illustrate the capability to modify aircraft response to gusts through ride control systems. Requirements to strengthen application of existing criteria to design of airplane ride control systems are given. Chief among these areas are the need for improved ability to handle human response to frequencies of vibration below 1.0 Hz and in validation of thresholds for extended exposure to vibration. Test data are also discussed which show the need to consider impact of ride environment on time to complete crew tasks, in addition to the more frequent concern with impact on performance errors.

USAF NON-COMBAY EJECTION EXPERIENCE 1968-1973 INCIDENCE, DISTRIBUTION, SIGNIFICANCE AND MECHANISM OF FLAIL INJURY

W. Steves Ring, James W. Brinkley, and Frank R. Noyes. In AGARD Biodyn. Response to Windblast Jul. 1975 8 p. refs. (For availability see N75-32716 23-51)

The USAF noncombat ejection experience during the period 1968-1973 is reviewed attempting to characterize the incidence. distribution, significance, and mechanism of fiail injuries. The overall incidence of flail injury is 7% in which 4% involved injuries of a major type. The distribution of injuries is characterized by (1) an absence of major head and neck flail injury, (2) a predominance of proximal over distal injury, and (3) in marked contrast to earlier date, a slight predominance of upper over lower extremity field injury. The importance of analyzing the forces acting upon the limbs as well as having a clear understanding of the mechanisms of failure is discussed and the need for improved limb restraints is emphasized

N75-32718 Italian Air Force Military School of Aviation

ACCIDENT STATISTICS RELEVANT TO WINDBLAST R. E. Noble and S. W. Olsen in AGARD Biodyn. Response to

Windblast Jul. 1975 4 p. refs (For availability see N75-32718 23-51)

During the period 1966-1974 injuries were significant problems in ejections from Canadian Forces (CF) aircraft. There were ninety nonfetal ejections. Of these, eight crew members escaped free from injuries, sixty-three received minor injuries. and nineteen received serious injuries. An analysis of the injury patterns indicates that they occurred at both low and high speeds. Specific problems are addressed and recommendations are made to enhance aircrew safety during ejection.

N75-32720 Royal Naval Scientific Service, London (England). PATHO-PHYSIOLOGICAL EFFECTS OF WIND BLAST FROM

CONVENTIONAL AND NUCLEAR EXPLOSIONS
J. S. P. Rawlins In AGARD Blodyn. Response to Windblast
Jul. 1975 5 p refs (For evallability see N75-32716 23-51)

The patho-physiological affects of wind blast resulting from conventional and nuclear explosions are analyzed and related to the effects of wind blast encountered in high speed aircraft ejections and in airborne sircraft breakup, and to some instances of ground impact. It is suggested that data derived from studies of explosive blast effects may contribute to the enalysis of aircraft accidents, and to the development of protective equipment for the crews of high performance aircraft.

N75-32721 Centre d'Essais en Vol. Bretigny-sur-Orge (France). INJURIES OBSERVED FOLLOWING HIGH-SPEED EJECTIONS IN THE FRENCH AIR FORCE (LESIONS OBSERVEES APRES EJECTION A GRANDE VITESSE DANS L'ARMER DE L'AIR FRANÇAISE]

R. P. Delahaye (Hopital Begin), B. Vettes, and R. Auffret. In AGARD Blodyn: Response to Windblast Jul. 1975 8 p. refs in FRENCH (For availability see N75-32716 23-51)

A review is presented concerning 256 ejections from French Air Force aircraft at speeds ranging between 0 and 750 knots, that took place between 1950 and 1974. The following overall statistics are given: 47 ejections (18 %) were fatal, while 209 (82 %) were successful. A total of 130 helmets (81 %) and 30 masks (15 %) were lost. In the case of ejections performed at speeds above 400 knots (23 cases), air blast effects increase the severity of injuries to personnel and demage to equipment. The percentage of fatalities remains at 18 %, while the percentage of injured aircrews reaches 78 % (as opposed to an overall percentage of 35 %); 78% of halmets and 40% of masks are lost. Only one pilot landed unhurt injuries range from ecchymoses to avulsion of limbs. The above data agrees fairly well with comparable data from other air forces. Three cases are discussed in detail.

AN ARM RESTRAINT SYSTEM FOR EJECTION SEATS IN

MIGH PERFORMANCE AIRCRAFT
P. H. R. Gill In AGARD Biodyn. Response to Windblast Jul.

P. H. R. Gill In AGARD Biodyn. Response to Windblast Jul. 1975 4 p. refs (For availability see N75-32716 23-51) A restraint system designed for high performance aircraft.

A restraint system designed for high performance aircraft from which ejection at high speeds is likely is described. The system evolved comprises a seat portion consisting of two fixed length tapes, and a man portion incorporated into a sleeved life preserver. Each seat tape is enclosed in a fabric tube which allows automatin disconnection of the two portions during emergency ground egress. The system functions on ejection by retracting the arms in a similar manner to leg restraint systems. The development, testing and performance of the system is described. Limited studies have demonstrated that the proposed rate of arm retraction is physiologically acceptable both with the hands on the firing handle and under simulated commanded ejection. The arm restraint tapes can be routed unobtrusively to prevent interaction upon routine cockpit movement during normal flight. The performance of the arm restraint system during ejection tests using dummies is also described.

B, N. T. Wells In AGARD Radiation Hazards Aug. 1975 7 p. refs (For availability see N78-11693 02-51)

Ultrasound, which is a form of energy consisting of mechanical vibrations the frequencies of which lie above the range of human hearing, travels through media in the form of waves. At frequencies of tens to hundreds of kilohertz, ultrasound may be generated and detected by magnetostriction; at higher frequencies, plezoelectric, and particularly ferroelectric, transducers are used. At megahertz frequencies, ultrasonic powers are most conveniently measured by radiation pressure detectors, or by calorimetry. In biological soft tissues, ultrasonic waves are usually in the iongitudinal mode, and travel at velocities of around 1 500 m/s. The shape of ultrasonic field depends on the size of the transducer in relation to the wavelength. Focusing systems of quite small dimensions can be used to produce high intensities at megahertz frequencies. Specular reflection occurs at discontinuities in characteristic impedance which are large in relation to the wavelength; energy is scattered by smaller discontinuities within biological materials.

BIOPHYSICS - ENERGY ABSORPTION AND DISTRIBUTION

Arthur W. Guy In AGARD Radiation Hazards Aug. 1975 14 p refs (For availability see N76-11693 02-51)

The interpretation of the biological effects observed in tissues exposed to EM fields requires a complete quantitative description of the fields within the tissues. These fields are complex functions of the source configuration, shape and size of the exposed subject, and the frequency. The average and maximum absorbed power density may vary over many orders of magnitude for the same applied field intensities. Depending on conditions, power absorption may be predominantly at the surface of the subject or may be affecting only superficial tissues in the interior of the subject affecting deep tissues.

M76-11697 Air Force Systems Command, Brooks AFB, Tex. Radiation Physics Branch. ELECTROMAGNETIC RADIATION EFFECTS ON THE EYE.

John C. Mitchell In AGARD Radiation Hazards Aug. 1975 6 p. refs (For availability see N76-11693 02-51)

The purpose is to analyze, collectively, the EMR research studies on ocular effects and provide an overview of the practical aspects of this problem today. The principal conclusions from

this effort are (1) The acute thermal insult from high intensity EMR fields is cataractogenic if intraocular temperatures reach 45:55 C. (2) The EMR exposure threshold is about 100-150 mW/sq cm applied for about 60-100 minutes. (3) There does not appear to be a cumulative effect from EMR exposures unless each single exposure is sufficient to produce some irreparable degree of injury to the eyes.

MICROWAVE INDUCED ACQUISTIC EFFECTS IN MAM-MALIAN AUDITORY SYSTEMS

Arthur W. Guy and Chung-Kwang Chou In AGARD Radiation Hazards Aug. 1976–17 p. refs (For availability see N78-11893 02-51)

Pulsed microwave fields with incident energy densities of 20 to 40 micro Joule per sq cm per pulse will produce responses in the auditory system of man and animals similar to those produced by auditory stimuli. Recent studies indicate that the responses may be originated from high frequency vibrations induced in the head of the exposed subject by a transient thermal expansion of tissue due to the rapid absorption of the pulsed microwave energy.

ENGINEERING CONSIDERATIONS AND MEASURE-MENTS

Arthur W. Guy In AGARD Rediation Hazards Aug. 1975 36 p. refs (For evailability see N76-11693 02-51)

Quantitation of the biological effects in subjects exposed to electromagnetic fields requires that both the fields in the environment and within the exposed tissues be measured. Fields in the environment can be measured by means of standard off-the-shelf field survey moter sensors consisting of small dipoles with diode or thermocouple-type transducers for converting microwaves or fif energy to proportional electrical signals. Fields and associated absorbed power density in the tissues can be measured by means of thermocouples, thermistors, fiber optic liquid crystal sensors, and thermography. The quantitation of fields associated with exposure of test subjects can be significantly simplified by a judicious choice of exposure techniques. Author

ELECTROMAGNETIC INTERFERENCE OF CARDIAC PACEMAKERS

John C. Mitchell In AGARD Hadiation Hazards Aug. 1975 10 p refs (For-availability see N76-11693 02-51)

The effect of electromagnetic radiation (EMR) on cardiac pacemakers is a unique bioeffects problem. Current test procedures, including methods to simulate pacemaker implant conditions and the use of fiber optics instrumentation techniques for cardiac simulation and pacemaker interference evaluation, are presented. Test results and their clinical significance are discussed for different types of EMR emissions including microwave ovens. electrical appliances, gasoline engine ignition, rader, and intense electromagnetic pulse generators. Threshold values for pacemaker electromagnetic interference (EMI) range from 10 V/m for the more sensitive devices to greater than 300 V/m for the less susceptible devices. Such EMI threshold values are further modified by the frequency and pulse width of the incident EMR signal. Maximum interference coupling appears to occur at frequencies between 100 and 500 MHz and the EMI threshold is inversely proportional to pulse width over the range from one microsecond to several milliseconds. The ultimate biological effect is dependent on the characteristics of the EMR source, the proximity of the pacemaker user to the source, the attenuation afforded by body shielding and orientation, and the state of-health of the pacemaker user. The test results presented provide considerable evidence that many manufacturers have recognized EMI as a potential bigeffects problem and have taken the necessary corrective actions to build devices with good electromagnetic compatibility.

ON EMP SAFETY HAZARDS

Arthur W. Guy In AGARD Radiation Hazards Aug. 1975
7 p. refs (For availability see N76-11693 02-51)

The only two quantitative criteria presently available for setting of electromagnetic pulse (EMP) safety standards are: (1) the ANSI C95.1 Safety Standard based on limiting thermal insult at microwave frequencies, and (2) the thresholds for the stimulation of excitable membranes by electric durrent. The first is not realistic for application to the EMP since the induced currents and energy deposition in exposed tissue is not based on an applied field amplitude and duration relationship, but is related only to the rise and fall time of the applied field pulse. The induced currents in the tissues of man exposed to impulsive electromagnetic fields do not appear to be sufficient for stimulating action potentials.

PROTECTION GUIDES AND STANDARDS FOR MI-GROWAVE EXPOSURE

Sol M. Michaelson In AGARD Radiation Hazards Aug. 1975 6 p. refs (For availability see N76-11693 02-51)

The development of adequate and operable standards requires comprehensive evaluation of information obtained from animal experiments and surveys of individuals exposed occupationally. The criteria to be used in evaluating experimental results of microwave exposure and the intersoting variables in such assessment requires the exercise of informed judgement, Since there are variations in the criteria used in many countries, these have to be understood and evaluated. Guides and exposure levels in force today appear to be entirely safe. So far, there is no documented evidence of injury to military or industrial personnel or the general public from the operation and maintenance of radars and other RF and microwave emitting sources within the 10 mW/sq cm limit of exposure. There is no evidence of hazard to man from RF and microwaves under normal conditions of operation and exposure. Nevertheless, concern has been aroused about the safety of personnel in Intense RF fields close to transmitting antennas operating in the frequency bands below 30 MHz. Such environments are in general of a near-field type which precludes the measurement of power flux. Since hazard evaluation in this frequency range is a function of measurement in the near-field, attention should be paid to the problems inherent in such measurement

THE PATHOPHYSIOLOGY OF HIGH SUSTAINED IS GUB 2 ACCELERATION, LIMITATION TO AIR COMBAT MAN-DEUVERING AND THE USE OF CENTRIFUGES IN PER-FORMANCE TRAINING

Naville P Clarke, ed. (Texas A and M Univ., College Station) and Sidney D Leverett, Jr., ed. (School of Aeruspace Med.) Oct. 1976 77 p. refs. Papers presented at the Aerospace Med Panel Specialists' Meeting, Copenhagen, 5-9 Apr. 1976 (AGARD-CP-189) Avail: NTIS HC A05/MF A01

The risk of significant cardinvascular change to a tactical fighter pilot from exposurs to aerial combat accelerations such as those postulated for new high performance aircraft is intestigated. Miniature swine were used as animal models to study the effects of high sustained acceleration. The seatback angle was assessed in relation to the psycho-physiological and physio-chemical changes in the human body. The utilization of the human centrifuge for training military pilots for air combat maneuvering i Gz stress is covered including the stress response and stress tolerance during the maneuvers. Centrifuge training improves the pilot's ability to effectively perform in the high G environment. For individual titles, see N77-11845 through N77-11653.

N77-11645# School of Aerospace Medicine, Brooks AFB, Tex. CHANGES IN CLINICAL CARDIOLOGIC MEASUREMENTS ASSOCIATED WITH HIGH +G SUB 2 STRESS

Kent K. Gillingham and Phelps P. Crump In AGARD The Pathophysiol of High Sustained I G sub z Acceleration, Limitation to Air Combat Manoeuvering and the Use of Centrifuges in Performance Training Oct. 1976 9 p refs (For primary document ages N77-11644 02-51)

Avail: NTIS HC A08/MF A01

Because of reports of subendocardial hemorrhage and myofibrillar degeneration in animals exposed to sustained high G loads, questions have been raised regarding the safety of exposing pilots and human subjects to the similar G-stress levels likely to be encountered in the new high performance fighter aircraft. Noninvasive clinical cardiologic data, including ECGs. vectoreardingrams, systolic time intervals, and maximal treadmill stress tests, were obtained from two groups of subjects before and at several times after exposure to high-G stress. The group exposed to the greater G stress developed moderate cutaneous petechlasis and had other minor physical findings after the G stress, but showed few significant changes in cardiologic data: serum total CPK and LDH levels rose, and preselection period shortened at 48 h poststress. The group exposed to the lesser G stress had no symptoms following the G stress, but the vectorcardiograms revealed transient 1-loop angle changes. and preejection period measured at one week poststress was significantly decreased. Because the surum anzyme changes were noncerdiac in origin, and because the few other changes were not in a direction indicative of cardiac damage, the G stresses imposed were not significantly injurious Author

N77-11646# School of Aerospace Medicine, Brooks AFB, Tex. VENTRICULAR PATHOLOGY IN SWINE AT HIGH SUSTAINED + G SUB 2

William F. MacKenzie and Russell R. Burton In AGARD The Pathuphysiol of High Sustained i G sub z Acceleration, Limitation to Air Combat Manoeuvering and the Use of Centrifuges in Performance Training Oct. 1976 3 p. refs (For primary document see N77-11644 O2-51). Avail: NTIS HC AO5/MF AO1

Study of miniature swine has shown two distinct types of cardiac pathology as the result of exposure to HSGz. Grossly visible endocardial hemorrhage of varying dagrees of severity occur consistently. In severe cases damage to Purkinje fibers is adequate to explain some of the ECG changes that have been found. A stress impocardiopathy is also found characterized by randomly distributed single or grouped, degenerate and dead muscle fibers surrounded by normal appearing fibers. Electron microscopically the lesion is characterized by profound changes in the contractile myofibrils known as myofibrillar degeneration. These changes have also been found in Purkinje fibers. It appears that the subendocardial hemorrhage is related to the combination of tachycardia, strong contractions (positive inotropism), and a hypovolemic ventricle. The stress myocardiopathy has a distinctly different and complex stiology. The ultrastructural lesions are not indicative of a primary hypoxic insult although hypoxic undoubtedly contributes.

PSYCHO-PHYSIOLOGICAL AND PHYSIO-CHEMICAL ABBESSMENT OF ACCELERATION INDUCED CHANGES IN HUMANS POSITIONED IN VARIOUS SEATBACK ANGLE CONFIGURATIONS

Victoria M. Voge, Harald J. VonBeckh, and Jeffry S. Bowman In AGARD. The Pathophysiol. of High Sustained +G sub z Acceleration, Limitation to Air Combat Manoeuvering and the Use of Centrifuges in Performance Training. Oct. 1976. 9 prefs (For primary document see N77-11644 02-51). Avail NTIS HC A05/MF A01.

A series of high-G tests were conducted on pilot/subjects using the multi-posture adjustable centrifuge test seat. An increase In human tolerance to sustained acceleration was demonstrated by employing several seat configurations. A significant increase in G tolerance was demonstrated with each increase in seatback angle. The position of the lower legs made no significant difference. Ten subjects between the ages of 20 and 44 with various body builds and G experience took part. All had passed the equivalent of a first class Navy flight physical, including complete spine X-rays and a determination of mental status. Some had previous G experience, either operational or in the human centrifuge, others did not. They were taking no aignificant medications at the time of the program, and were encouraged to eat normally, to get sufficient rest, and to avoid alcoholic beverages. The testing was carried out over a period of six weeks. The tests were carried out on the analog computer controlled, double gimbaled, dynamic flight simulator which consists of a human centrifuge having a fifty foot radius arm with the capability of attaining 40 G's in 7 seconds.

CENTRIPUGE ASSESSMENT OF A RECLINING SEAT David H. Gleister and Brian J. Lisher In AGARD The Pathophysiol. of High Sustained + f6 sub z Acceleration, Limitation to Air Combat Manoeuvering and the Use of Centrifuges in Performance Training Oct. 1976 8 p refs (For primary document see N77-11644 02-51)

Avail: NTIS HC A05/MF A01

A reclining seat has been built which would give a pilot a algnificant increase in acceleration tolerance whilst maintaining adequate forward vision. The effect of anti-G suit inflation has been investigated using three different pressure regimens, and positive pressure breathing (PPB) has been used to counter the added inspiratory effort which resulted from the considerable $\pm G$ acceleration vector. The reclining seat alone gave an increase in tolerance of 1.4G when compared with a conventional seat; anti-G suit inflation afforded a further 1.0 to 1.6G; and PPB a further 1.0G. The combination led to relexed greyout thresholds which averaged 7.4G in nine subjects. PPB produced a significant increase in vital dapacity and restored this expiratory reserve volume to near normal levels. Subjectively, breathing became much easier. The closing volume of the lung was increased by acceleration, but was not significantly affected by PPS. However, the increase in expiratory reserve volume with PPB should lead to less sirway closure during tidal breathing, with a consequent increase in arterial oxygen levels and a decreased susceptibility to acceleration atelectasis. A seat in which a near supine position is adopted with respect to the G ventor, when used in conjunction with an anti-G sult and positive pressure breathing, will result in a G tolerance which is in more accord with the performance of modern military aircraft.

N77-11648# Texas Univ., Galveston. Medical Branch. CORONARY FLOW AND MYOCARDIAL BIOCHEMICAL RESPONSES TO HIGH SUSTAINED : G SUS z ACCELERATION

H. L. Stone, L. A. Sordahi, R. T. Dowell, J. N. Lindsey, and H. H. Erickson (School of Aerospace Med.) In AGARD. The Pathophysiol of High Sustained +G sub z Acceleration, Limitation to Air Combot Manoeuvering and the Use of Centrifuges in Performance Training Oct 1978 8p :efs (For primary document see N77-11644 02-51)

Avail: NTIS HC A05/MF A01

In order to determine directly the myocardial response to + Gz acceleration, miniature swine were used as the experimental subjects. Some of the animals underwent surgical implantation of flow probes around the left circumflex coronary artery and a solid-state pressure transducer in the left ventricular cavity. All of the unaneathetized instrumented subjects were exposed to multiple + Gz acceleration levels for 60 to 120 seconds on a human centrifuge. Other subjects were exposed to a single acceleration level for 120 seconds and the hearts removed for

biochemical analysis 1 to 2 hours later. Mitochondria and a lysosomal fraction were isolated from the left ventricle of all animals. Mitochondrial analysis of ADP.O ratio, respiratory control index (RCI), oxygen uptake (QO2) and calcium uptake were made. Free and bound acid phosphiatase measurements were made in the lysosomal fraction. Left circumflex coronary artery flow (LCCF), heart rate (HR), left ventricular pressure (LVP), and the rate of rise of LVP (P), were measured in the instrumental animals. LVP and HR increased at all levels of acceleration studied while P increased initially but would decline later. LCCF decreased at all levels of acceleration stress. The mitochondrial ADP:O ratio and the RCI were unchanged but the QO2 and calcium uptake were increased at 9 ± Gz. Free acid phosphatase increased at the same level of acceleration.

EFFECT OF SUSTAINED +G SUB 2 ACCELERATION ON CARDIAC OUTPUT AND FRACTIONATION OF CARDIAC OUTPUT IN AWAKE MINIATURE SWINE

Robert L. Hamlin and Sidney D. Leverett, Jr. (School of Aerospace Med.) In AGARD. The Pathophysiol. of High Sustained + G sub z Acceleration, Limitation to Air Combet Manoeuvering and the Use of Centrifuges in Performance Training. Oct. 1976 6 p. refs (For primary document see N77-11644-02-52) Avail: NTIS. HC A06/MF A01

Effects of sustained + Gz on cardiac rhythm and output, and on fractionation of cardiac output (CO) were studied in 12 or miniature swine centrifuged, while swake, to either + 3Gz or + 5Gz. CO and its subfractions were measured by injecting radiolabeled microspheres into the left atrium. Percentage of CO perfusing most organs fell precipitously during + 6tiz, while that to the heart increased by twofold and that to the pelvic musculature remained nearly constant. At + 3Gz percentage perfusing most organs fell, but that to heart and all skeletal muscle rose twofold. When regional flow decreased, it decreased most to the eye, and next to liver, cerebrum, and renal cortex it decreased least to the midbrain, spleen, renal medulia and gut. The profound changes in CO and fractionation of CO in swake ministure swine subjected to + Gz may represent a summation of: reflex response, a waterfall effect, or deformation of nutrient arteries.

UTILIZATION OF HUMAN CENTRIFUGE FOR TRAINING MILITARY PILOTS IN THE EXECUTION OF PROTECTIVE STRAINING MANEUVERS

C. A. Ramacci and G. Meinen In AGARD. The Pathophysiol. of High Sustained + G sub z Acceleration, Limitation to Air Combat Manoeuvering and the Use of Centrifuges in Performance Training Oct. 1976. 3 p. (For primary document use N77-11644 02-51) Avail NTIS. HC A05/MF A01

The importance of the utilization of human centrifuges in the training of pilots in a rational execution of protective straining maneuvers is investigated. A group of young military pilots were submitted to 3 Gz for comparatively long durations. During the first centrifuge run the subjects were instructed to refrain from performing any voluntary straining maneuvers. Later, the same subjects were submitted to the same accoleration pattern, accompanied, this time, by the execution of the aforesaid straining maneuvers Exposures to G were repeated Changes in performance and in tolerance to G were evaluated by recording morphological changes of EXG and heart rate. Subjective feelings of pilots were recorded.

THE USE OF A FIXED BASE SIMULATOR AS A TRAINING DEVICE FOR HIGH SUSTAINED OR ACM (AIR COMBAT MANEUVERING) +G SUB 2 STRESS

S. D. Leverett, Jr. and R. R. Burton. In AGARD. The Pathophysiol. of High Sustained + G sub z Acceleration, Limitation to Air Combet Manoeuvering and the Use of Centrifuges in Performance Training Oct. 1976. 8 p. refs. (For primary document see N77-11644 02-51).

Avail: NTIS HC A05/MF A01

The imposition of 'Gz stress on 92 highly experienced tactical air command fighter pilots is investigated. A typical class of 22 of these pilots had an average of 1351.66 fighter hours, and were 29.04 years of age (1 or - 0.54). In this same class of 22 fighter pilots they estimated the highest G that they had ever pulled was 1 or - 9.0 Gz for 6.4 sec. From this data it was apparent that fighter pilots flying the F4E Phantom jet did

not pull high sustained G. Therefore a centrifuge program was initiated in order to train pilots at high sustained G and at ACM G. The profile used was as follows: (1) +3 Gz/15 sec . this was an orientation run in order to familiarize the pilot with the centrifuge environment; (2) +5 Gz/45 sec - this extended run was designed to enable the pilot to learn to pace his breathing and straining maneuver properly while being exposed to G sufficient to cause the anti-G suit to inflate: (3) a final ACM type profile that exposed him initially to 15 Gz/10 sec and then proceeded to +8 Gz/30 sec, decelerated to +5 Gz/10 sec and finally the centrifuge was brought to a halt. Under these conditions the 92 pilots' heart rate and rhythm was continuously monitored. Resting heart rate for this larger group prior to initiation of the run averaged 115.93 bpm. While the maximum heart rate at ±8 Gz was 167.04 bpm in all instances using a students t-test, the P value is < .001 when the heart rates at any G level are compared to the pre-run control heart rates. All of the pilots were able to complete the proposed series of runs after receiving training by the centrifuge group without a loss of vision.

N77-11653# EEG Research Inst., Osio (Norway), STRESS RESPONSE AND STRESS TOLERANCE IN FIGHTER PILOTS DURING 6 MANOEUVERS

C. W. Sem-Jacobsen In AGARD The Pathophysiol. of High Susteined +G sub z Acceleration, Limitation to Air Combas Manoeuvering and the Use of Centrifuges in Performance Training Oct. 1976 6 p (For primary document see N77-11644 02-51) Avail: NTIS HC 405/MF 401

EEG and EKG have been monitored from 250 active fightur pilots flying combat training involving repeated 6 G turns and pullups. 50 students and 9 pilots have been monitored while riding in the back seat of two seater fighters going through the same manosuvers. More than half of those pilots who had committed pilots error were unconscious with convulsions following 6 G manosuvers. Gross EEG changes were seen in the EEG. Studies of the EKG and heart rate illustrates the cardio-vascular response. The well suited pilots had a quick response with increase of heart rate when needed to maintain adequate blood supply to the brain. The unsuited groups demonstrate a slow, unsufficient cardiac response leading to brain-anoxis unconsciousness and convulsion. The student pilots and the 9 pilots fell in the same two different categories indicating a basid difference in the functioning of the autonomic narvous system in these two groups.

MAN AT HIGH SUSTAINED + Gz ACCELERATION

R Burton (School of Aerospace Med.), S. D. Leverett, Jr. (School of Aerospace Med.), and E. D. Michaelson (Mt. Sinai Hosp.) Mar 1974 31 p refs

(AGARD-AG-190; AGARDograph-190) Avail: NTIS HC \$4.75 CSCL 08P

Man has tolerated +9Gz for 45 sec and +8Gz for 80 seconds. Physiological changes and tolerance limits in a sustained high acceleration environment are expressed by (1) high heart rate: (2) reduction in SaO2, (3) cardiac arrhythmia, and (4) subject fatigue. The effects of HSG are marked in terms of gas exchange and arterial hypoxia. Fatigue appears to be the critical factor regarding human limitations to HSG, and arterial desaturation appears to be the limiting factor in subjects using a reclining seat to prevent fatigue.

When technology became available to collect and analyze expired air, the measurement of maximal oxygen consumption IVO2 max) was considered advantageous in evaluating functional aspecity. Tests were specifically designed to measure this physiological parameter. Maximal seroble working capacity is defined as the work level at which oxygen consumed falls to increase linearly with further increases in workload and the oxygen donsumption at this point is called VO2 max. A study was designed to compare VO2 max and other physiological parameters measured during three standard protocols and to evaluate the reproducibility of each.

EPIDEMIOLOGIC RISK FACTORS OF FLUSH-RECYCLE TOILETS IN AIRCRAFT

Wolfgang H. Fischer In AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sep. 1975 2 p (For availability see N76-14758 05-52)

In connection with emergency air transports from areas of low hygienic standards and presence of important infectious diseases, laboratory tests and field trials disclosed a number of serious hygienic deficiencies which were taking an exceedingly critical course during middle range and long distance flights and also by exposal of ground servicing personal and vehicles to infectious waste material. It is shown that tollet sanitation systems presently used in stillners do not meet the standards required for the health of air crews and passengers. Commonly used sanitary fluids for toilet operation are presented and their quality discussed. Recommendations are given to improve the aircraft toilet sanitation.

N76-14760 Air France, Parls. Service Medical Central TRANSPORTATION OF PASSENGERS WITH CONTAGIOUS DISEASES ON AIRLINERS (LE TRANSPORT DES MALADES

CONTAGIEUX EN AVION DE LIGNE | Michel Perin in AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sep. 1975. 8 p. refs. In FRENCH, ENGLISH summary (For availability see N76-14758. 05-521

The problems related to the transportation of passengers with contagious diseases on strillners were discussed. It was pointed out that the refusal of most airlines to transport such passengers can sparcely be justified by reference to either laws or regulations, it introduces the risk of arbitrary, mistaken, or prejudiced conduct and it can cause serious harm to certain patients it also does not seem logical since airlines learn about only a small fraction of the contagious persons who travel, and public health is much more greatly endangered by unknown contagious persons. It was concluded that sirlines should continue to refuse to fransport unly those passengers having diseases characterized by vomiting or serious diarrhea or transmitted through the air, if it is impossible by simple means to avoid the risk of contaminating other travellers and flight craw members who might be receptive.

FOOD POISONING OBSERVED WITH AIRPLANE CREW AND PASSENGERS DEPENDING ON AIRPLANE OPERA-TIONS

R Schubert In AGARD Aeromedical Implications of Recent Experience with Communicable Disease. Sep. 1975. 3 p. refs. (For availability see N76-14758 05-52)

Many food poisonings can more easily be caused during air plane operations. They can create even more serious problems than on earth. In this connection they can be caused during the flight if it is of long duration and even bring about the symptoms of the illness. More frequently, however, they have been acquired before. Sometimes a gastrointestinal disturbance, the traveller's disease, can be observed appearing like a food poisoning without being such in the original sense. On flights from certain regions

THE RESERVE OF THE PERSON OF T

of the globe, especially from the har best, one must expect cases of food poisoning in the air traffic more often than from other countries

N76-14762 Bayerische Landesimpfanstalt, Munich (West Germany)

IMPORTATION, DIAGNOSIS AND TREATMENT OF SMALLPOX, CHOLERA AND LEPROSY

H. Chr. Huber, V. Hochstein-Mintzel, and H. Stickel. In AGARD Aeromedical Implications of Recent Experience with Communicable Disease. Sep. 1975. 4 p. refs (For availability see N76-14758 05-52)

Since 1957 a total of 11 cases of smallpox have been introduced into the FRG. The final diagnosis was usually delayed until the 10th day after the onset of clinical symptoms. The diagnosis of variols must be supported by epidemiological data and laboratory tests. Epidemiological data refer to travel in endemic areas, the probability and time of contact, and the resulting incubation period. Laboratory examination is usually restricted to three tasts, serological examination for hemagglutination inhibiting antibodies electron microscopy of skin scrupings, and virus isolation on the chorioaliantoic membrane of embryonated eggs. The importation of cholers and leprosy bears minor problems as to the possible spread of the diseases. Introduction of cholera cannot be avoided by public health measures. An endemic spread, however, does not need to be considered in countries of appropriate standards of public hygiene. The prognosis of the disease is quite favorable, provided that proper therapy is initiated in the party stages.

TRANSPORTATION BY AIR OF A LASSA FEVER PATIENT IN 1974

Horst H. Renemann In AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sep 1975 5 p. refs (For availability see N78-14758 05-52)

Lassa fever, also known as arenavirus disease and Casals' disease, was recognized for the first time in 1989 in Lassa, Nigeria. Its fatulity ratio has been high in clinically observed dases; 10 out of 22 infected physicians and medical workers died of it. The person-to-purson transmission probably takes place when sirborne viruses from the sore mucous membrances in the mouth and pharynx are expelled by breathing, talking and coughing. A German patient with arenavirus, Dr. Mandrella, was transported from Nigeria to Germany in March 1974, by Condor Bosing 707-430 manned by a volunteer flight crew of Lufthansa The special preparation of the plane to prevent transmission of airborne viruses to the flight crew and other measures taken against contamination will be described. A. J. Clayton. In AGARD. Aeromedical Implications of Recent Experience with Communicable Diseases. Sep. 1975. 4 p. refs. (For availability see N76-14758 05-52)

The clinical features of Lassa Fever are briefly discussed and the epidemiology of the disease is outlined with respect to the five recorded outbreaks between 1969 and 1974. The Canadian Government having become involved in two potential six evacuations of patients from West Africa is concerned over the risks to medical flight teams and receiving hospital personnel. in the event of cases of Lasua Fever being repatriated to Canada A survey is being carried out on Canadian Forces long range transport aircraft to study the interobiological environment within two types of aircraft during flights by dispersing nonpathogenic organisms. The objective is to determine the optimum location for a patient with a highly infectious disease and to ensure minimal transmission of organisms. Author

INTERNATIONAL QUARANTINE FOR CONTROL OF MOSQUITO-BORNE DISEASES ON GUAM

Wesley R. Nowell In AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sep 1975 8 p. refs (For availability see N76-14758 05-52)

The initial mosquito survey of Guam conducted in 1936 revealed the presence of five indigenous species. Subsequent surveys showed a steady climb to fifteen species in 1969, and a dramatic jump to thirty-five by 1972. Japanere B encephalitis. and filariasis, five primary mosquito-borne diseases known to

occur on Pacific Islands, have been found on Guam, and trends of the diseases are emphisized. The Island of Guam is centrally located in the Western Pacific and aircraft are implicated in the introductions of new mosquito species. Chronic problems associated with aircraft quarantine inspections and insect control procedures are described, and methods to curb the introduction of new mosquito species and their associated diseases are discussed.

AN EPIDEMIC OF CHIKUNGUNYA IN THE PHILIPPINE ISLANDS: POSSIBLE ROLE OF AIRCRAFT DISSEMINA-TION

George D. Lathrop and Paul J. Homme In AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sep. 1975 6 p. refs (For availability see N76-14758 05-52)

Twin outbreaks of chikungunya, a Group A arbovirus, are analyzed that occurred on the Island of Negros, Republic of the Philippines during 1968-1969. Epidemiologic data derived from interviews, serologic, and virologic testing showed that young and middle aged people were immunologically susceptible, and that the disease was transmitted in three week waves by the mosquito, Aedes albopictus, Inferential evidence suggested that acquired immunity due to an apparent 1920 chikungunya epidemic accounted for a lower attack rate in the elderly population. Chikungunya was probably introduced into Negros by aircraft or ships from Manila, where a smaller outbreak had been documented in 1967-1968. The outbreaks on Negros subsided naturally prior to increased mosquito abatement and public health control measures. Unconfirmed clinical evidence suggested that the disease was disseminated into the adjacent islands of Cebu and Mindanao.

THE ATTENUATED LIVE SMALLPOX VACCINE, STRAIN MVA RESULYS OF EXPERIMENTAL AND CLINICAL STUDIES

V. Hochstein-Mintzel, H. Stickel, A. Mayr, H. Chr. Huber, H. Schaefer, and A. Holzner. In AGARD. Aeromedical implications of Recent Experience with Cummunicable Disease. Sep. 1975. B.p. refs. Prepared in cooperation with Inst. fuer Mikrobiol.. Muenchen (West Germany) (For availability see N78-14758-05-52).

in an attempt to basically after and improve smallpox vaccination, the use of an attenuated strain of vaccinia virus was proposed. Attenuation was effected through more than 500 continuous passages in chick embryo fibroblast cultures. Animal experiments showed the complete absence of neurovirulence for the attenuated strain. The favorable experimental results led to a field study of primary vaccinations in the human. The recommended procedure was to administer 0.1 ml of attenuated vaccine intradermally, followed by conventional cutaneous smallpox vaccination 7 to 28 days later. The results may be summarized as follows: the local reaction to the attenuated vaccine merely amounted to slight reddening and infiltration at the site of injection with complete absence of typical vaccinal lesions. Untoward systemic reactions were not observed. The subsequent cutaneous vaccination resulted in 84% major reactions and 9% equivocal reactions. Seven percent remained negative, 78% of the takes were of the accelerated type, giving evidence of the Immunizing capacity of the attenuated strain. Author

COCCIDIOIDOMYCOSIS AND AVIATION

G. Apel and V. Grouls. In AGARD. Aeromedical implications of Recent Experience with Communicable Disease. Sep. 1976. 3 p. refs. Prepared in cooperation with Inst. of Pathol., Bonn-Venusberg (West Germany) (For availability see N76-14758.05-52).

In the age of transatiantic travel and mass tourism it can not be precluded that Coccidioidomycals will be brought to an as on the globe in which this disease has hitherto been unknown. Since the incubation period will last two to three weeks and occasionally also four weeks, the disease will frequently occur only after all passengers have long returned to their home countries. Considering the atriking similarity with the clinical picture of pulmonary tuberculosis, it is not surprising that in Europe the disease is diagnosed as tuberculosis, even more so since tuberculination may often be positive. The patients are then subjected to an anti-tuberculous therapy, which necessarily must remain without success in such cases. If an exact case history

including travels abroad and residences in endemic areas of Coccidioidomycosis can be established, a clue pointing to the true nature of the disease may be obtained.

THE INDUCTION OF INTERFERON AND SPECIFIC SMALLPOX IMMUNITY BY GRAL IMMUNIZATION WITH LIVE ATTENUATED POX VIRUS

A May, and H. Stickl /n AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sop 1975 5 p refs Prepared in cooperation with Inst. fuer Mikrobiol. Muenchen (West Germany) (For availability see N76-14758 05-52)

In the human, oral immunization with live attenuated virus was affected by the administration of virus-containing tablets. The procedure caused no untoward effect in primary vaccines. Subsequent skin testing and conventional cutaneous vaccination resulted in accelerated takes, demonstrating successful oral pre-immunization. Altenuated heterologous pox virus was shown to have a high interferon inducing capacity. Induction was optimal when the virus was applied to the mucous membranes of the oral cavity. Clinical trials showed significant effects of interforon induction in recurrent herpetic infections. Oral application of vaccines needs neither trained staff nor medical equipment, it confers short term non-specific protection from disease, followed by specific immunity. The usual contraindications to smalippa, vaccination need not be observed. Untoward effects, quite common to routine methods, are not to be expected.

INCIDENCE OF INFECTIOUS TROPICAL DISEASES DIAGNOSED ON FLYING PERSONNEI. [IMPORTANCE DE LA PATHOLOGIE INFECTIEUSE D'ORIGINE TROPICALE DANS L'EXPERTISE MEDIC: LE DU PERSONNEL NAVI-GANT)

R. Carre, J. Patacq-Crouzet, A. Didier, and J. Bastien. In AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sep. 1975. 6 p. in FRENCH (For availability see N76-14758 05-52).

Statistical data on the incidence of infectious tropical diseases diagnosed during the period 1969 to 1972 on French military and commercial flight crews was presented. The personnel examined were those making regular trips to Africa, Madagascar, the West Indies, and Reunion Island. The two diseases most widely detected were amebiosis (106 cases, including 13 severe cases localized in the liver and 93 cases localized in the intestinal tract) and malaria (45 cases, including 8 severe cases with encephalic and comatose involvements). The following other parasitic diseases were observed, bilharziasis (5 cases), filariasis (4 cases), stomatosis (2 cases), strongyfoldiasis (8 cases), and ankylostomiasis (5 cases). Most cutaneous diseases detected were of bacterial origin. Viral hepatitis was widely observed on personnel having travelled in Africa, and dengue was diagnosed on military personnel returning from the Pacific.

N76-14771 Tropen Inst., Hamburg (West Germany)
DIAGNOSTIC METHODS IN TROPICAL MEDICINE

Werner Mohr In AGARD Aeromedical Implications of Recent Experience with Communicable Disease Sep. 1975 3 p (For availability see N76-14758 05-52)

The doctor consulted by persons returning from overseas countries should have a certain knowledge of geographical medicine. He must know in which regions on the globe malaria occurs, and where intestinal diseases are provalent. A precise anamnesis of the patient's itinerary is most essential. During the physical examination the examiner is likely to recognize a number of symptoms which will help him along diagnostically. (1) Rashes and dischromia: (2) edemas: (3) lever; (4) enlargement of the liver; (5) enlargement of the spicen; (6) respiratory changes; (7) changes in stool (diarrhea); and (8) changes in urine (hematuria), to name but a few.

N76-14772 Bayerische Landesimpfanstalt, Munich (West Germany)

THE THREAT OF TROPICAL DISEASES AND PARASITOSES (SOME EPIDEMIOLOGICAL AND CLINICAL ASPECTS)

G. T. Werner, H. Chr. Huber, H. Stickl, and V. Hochstein-Minizel In AGARD. Aeromedical Implications of Recent Experience with Communicable Disease. Sep. 1975. 5. p. refs (For availability see N76-14758-05-52).

The rapid increase of travels to the warm countries has brought the threat of tropical diseases to our doors. Furthermore

a great number of people are in employment overseas Bosidos, the continuous influx of laborers, students or immigrants from tropical countries can create new medical problems. There is no real danger that tropical diseases are going to cause epidemics in the highly developed countries, as the hygienic standards prevent generalized outbreaks. There is, however, a substantial danger in the individual case due to missed or delayed diagnosis and treatment. Reviewed are those tropical diseases which are imported frequently or which present problems in the single case. Cosmopolitan diseases which are nice common in the tropics, like hepatitis, polio, tuberculosis are excluded.

N76-14773 Tropen Inst. Hamburg (West Germany)
AIR TRAFFIC AND THE PROBLEM OF IMPORTATION OF
DISEASES FROM THE TROPICS

Werner Mohr /n AGARD Aeromedical Implications of Recent Exportence with Communicable Disease Sep. 1975 3 p (For

availability see N76 14758 05-52)

It is not possible to deal with all diseases which could be imported from the tropics to Europe or the temperate climate zones respectively. However, helminthic diseases should be referred to briefly. The most frequent and important ones among them are hookworm infestation, bilharziosis (schistosomiasis) in all its various forms, and filariasis. Time and again it can be observed that persons returning from the tropics may have contracted a variety of infectious diseases, especially intestinal parasites. There are a number of measures that should be taken to give protection against the diseases described above (1) Protective inoculation against certain diseases and prophylactic medication; (2) it is of great importance to instruct physicians at home, i.e. in the temperate climate zones, in tropical diseases and their diagnosis; and (3) any person on return from the tropics should be subject to a close medical examination, in particular when such a person suffered from any disturbances of health during his stay in the tropics or is still suffering from such disturbances.

N76-17786# Advisory Group for Aerospace Research and Development, Peris (France). EFFECTS OF LONG DURATION NOISE EXPOSURE ON HEARING AND HEALTH

Milton A. Whitcomb, ed. (NSF) Nov. 1975-94 p. refs. Presented at the Aerospace Med. Panel Specialists Meeting, Toronto, 5. May

(AGARD-CP-171) Avail: NTIS HC \$5.00

There can be no doubt that noise exposures of durations greater than eight hours present a heard to the hearing of air crews flying noisy aircraft and, particularly, for those more susceptible crew members. Noise reduction around NATO eirports to insure public health is examined. Data are examined on the incidence of stress-induced pathologies such as ulcers or emotional disorders for those exposed to long-duration noise, as compared to nonnoise exposed individuals. Flight crews exposed to such long durations of noise were monitored both audiometrically and for abnormal incidence of cardiovascular disease, ulcers, and other psychosomatic complaints. Long-duration noise exposure to the moderate levels of noise that occur in aircraft cockpits was also studied. The rundamental mechanisms causing cochlear damage (mechanical and biological) are critically examined. For individual titles, see N76-17787 through N76-17799.

N78-17787 Ohio State Univ., Columbus. Dept. of Otolaryngol-

MODE OF COCHLEAR DAMAGE BY EXCESSIVE NOISE, AN OVERVIEW

David J. Lim and William Melnick In AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 6 p. refs (For availability see N78-17786 08-52) (Contract F33615-74-C-4049)

Damage to the cochles is examined and is believed to be caused by a physical or metabolic stress exerted on the sensory cells. Evidence to support both mechanisms is overwhelming, and is reviewed, injury can be brought about by the chemical or metabolic alteration in the surrounding medium. Beeldes apparent mechanical damage inflicted on the organ of Corti by the acoustic hyperstimulation, the evidence of metabolic damage to the sensory cells is subtle. The subtle changes include: (1) proliferation and vacuolization of endoplasmic reticulum in sensory cells. (2) swelling of mitochondria in both sensory cells and afferent nerve endings, (3) morphological alteration of stereocilia and (4) swelling and degeneration of stris vascularis. These findings imply that the high-energy-yielding enzyme systems are rendered inoperative in these cells, resulting in cell degeneration. Photomicrographs are shown.

TTS IN MAN FROM A 24-HOUR EXPOSURE TO AN OCTAVE BAND OF NOISE CENTERED AT 4 kHz
William Melnick /n AGARD Effects of Long Duration Noise

William Melnick In AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 8 p. refs (For availability see N76-17786 08-52) (Contract F33616-71-C-4049)

(AMRL-18-75-3)

Seven men were exposed to 24 hours of continuous noise in a sound field. The noise was an octave band centered at 4 kHz at two octave band levels. 80 and 85 db. Hearing thresholds were measured in one ear at 11 test frequencies ranging from 250 to 10,000 Hz prior to exposure and at selected intervals during and after exposure. Temporary threshold shift (7TS) reached asymptotic levels between 8 and 12 hours of exposure. Results indicate that maximum TTS occurs at 4 and 6 kHz. Asymptotic levels at the 80 db exposure level are 9.7 db for 4 kHz and 7.7 db for 6 kHz. With the 85 db noise level, these levels are 18.4 db and 16.5 db, respectively. Threshold shift for this subject group is less than would be expected from results of previous investigations, and is attributed to subject sampling bias. Author

N76-17789 Italian Air Force Medical Service of the 2d Air Region, Rome Sanitary Group - 1st Aerobrigade.
PROTECTIVE EFFECTS IN MEN OF BRAIN CORTEX GANGLIOSIDES ON THE HEARING LOSS INDUCED BY HIGH LEVELS OF NOISE

G. Maniero and G. A. Molinari (Padua Univ., Italy) in AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 6 p. refs (For availability see N76-17786 08-52)

It is known that the prolonged exposure to noise of intensity greater than 70-80 decibels produces a temporary rise of the acoustic threshold (TTS). Gangliosides, (glycolipids which seem to interfere with the transmission of nervous impulse), were used In preventing TTS rise. By means of ganglioside administration, a possible interference on the traumatizing effect of noise on the cochies was observed and studied. Following otologic and audiometric examination, 20 healthy male subjects were chosen. The TTS2 was nalculated, both in basel conditions and after ganglioside administration. Results indicate that the gangliosides. administered in opportune doses and modalities, are capable of preventing in all subjects the physiological rise in the hearing threshold after exposure to noise. In contrast, the nontreated subjects in the same experimental conditions have either the same TTS2 or show a large shift. Therefore, the positive fallure in shift, occuring in the treated patients, is most probably due to ganglioside offect.

N76-17790 Minnesota Univ., Minneapolis. Hearing Research Lab.

STUDIES OF ASYMPTOTIC TTS

W. Dixon Ward In AGARD Effects of Lung Duration Noise Exposure on Hearing and Health Nov. 1975 7 p refs Sponsored by Natl. Inst. for Occupational Safety and Health (For availability see N78-17785 08-52)

Ten young normal-hearing listeners were subjected to a series of exposures to 4000-Hz noise for neriods ranging from 2 to 24 hours. The esymptotic TTS (temporary threshold shift) was always reached in 8-12 hours with no suggestion of a sharp increase between 8 and 24 hours. Little difference could be seen in the rate of recovery from the TTS produced by 8- and 24-hour exposures. Results indicate that exposures longer than 8 hours are not unusually hezerdous. If there is an increased risk of eventual permanent hearing demage from repeated delity exposures longer than 8 hours. It probably comes from the fact that as the daily exposure becomes longer than 8 hours, the quiet Interval before the next exposure is shortened, so that the next day's exposure is begun with the auditory system still in a latiqued state.

N76-17791 Aerospace Medical Research Labs., Wright-Patterson AFB, Ohio.

ASYMPTOTIC BEHAVIOR OF TEMPORARY THRESHOLD SHIFT DURING EXPOSURE TO LONG DURATION NOISES

D. L. Johnson, C. W. Nixon, and M. R. Stephenson In AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 6 p. refs (For availability see N76-17786 08-52)

Exposure to a constant noise level (pink noise, i.e., jet aircraft noise) for more than 16 hrs has been shown by many investigators to cause a Temporary Threshold Shift (TTS) in hearing that remains

constant. This behavior, which is independent of exposure duration, is called Asymptotic TTS. Data are given which show that although TTS may remain constant, the recovery of hearing back to normalcy does depend on the duration of the exposure. Significant differences in recovery between a 24 hr exposure and a 48 hr exposure were observed. It is believed that for hearing conservation purposes, the time Air Force personnel should be allowed to recover from long duration noise exposures in quiet depends on the exposure duration. Suggested guidelines for assuring recovery of Asymptotic T7S are given and the research program aimed at improving these guidelines is discussed.

N76-17792 Defence and Civil Inst of Environmental Medicine. Downsview (Ontario). Behavioral Sciences Div.

THE INCIDENCE OF TEMPORARY AND PERMANENT HEARING LOSS AMONG AIRCREWS EXPOSED TO LONG-DURATION NOISE IN MARITIME PATROL

In AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 7 p refs (For availability see N76-17786 08-52) (DCIEM-75-RP-1073)

The CP-107 Argus has been in operation with the Canadlan Forces since 1957 as a long-range maritime patrol alroraft. The endurance capability of the aircraft is at least 24 hours at reconnaissance altitudes and speeds. Flight durations from 12 to 20 hours occur routinely, during which ambient noise levels at various crew and rest stations range from 90 to 99 dBA. An assessment of crew and operational problems arising from long-duration flights in the Argus shows that about half of the crew sustain temporary threshold shifts in excess of levels considered to be acceptable for long-term exposure. The hearing levels of 223 pilots, navigators and flight engineers were studied with career flying times in the Argus ranging from 2500 to 10,000 hours. Results of the study suggest that repeated long-duration noise exposure, as experienced in the aircraft, are not any more deleterious to hearing thresholds than is repeated exposure, at approximately equivalent intensity levels, in shortand medium-range aircraft.

N76-17793 Centro di Studi e Ricerche di Medicina Aeronautica e Spaziale, Rome (Italy).

PSYCHO-PHYSICAL PERFORMANCE OF AIR FORCE TECHNICIANS AFTER LONG DURATION EXPOSURE

Cesare A. Ramacci and Paolo Rota In AGARD Effects of Long Duration Noise Exposure on Hearing and Health

1975 3 p. refs (For availability see N76-17786 08-52)
Psychological and psycho-physiological tests were carried out (Toulouse Pieron test, flicker fusion test, reaction time) on 20 Air Force technicians, on duty at an aircraft maintenance and flight line, exposed to high level noise. Work conditions considered were: (1) continuous exposition to noise of about 120 db, for one hour and half; and (2) continuous exposure for five hours to 60-80 db noise, with transient increases up to 90-115 db. The technicians used, when necessary, individual or collective ear protection. The technicians were divided into 3 groups and given specific tasks to perform. The tests, carried out before and after noise exposure, do not show significant changes of task performance.

N76-17794 Institute of Aviation Medicine, Fuerstenfeldbruck (West Germany).

OF EAR PROTECTORS ON SOME THE EFFECTS AUTOMATIC RESPONSES TO AIRCRAFT AND IMPULSIVE

G. R. Froehiloh In AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 5 p (For availability see N76-17786 D8-52)

Three different types of ear protectors were evaluated for protection against jet aircraft noise and other noise. Autonomic nervous system responses were measured for 25 aubiects who participated in the study. Peripheral blood flow and electrodermal responses were also measured. Jet girdraft noise levels of 95 db. and other noises (a pistol shot) of 130 db were provided. Subjects were asked to select tile ear protector giving the greatest protection. Results are presented and discussed.

N76-17795 Caritro di Studi e Ricerche di Medicina Aeronautica e Spaziale. Rome (Italy)

INFLUENCE OF THE NOISE ON CATECHOLAMINE

G. Paolucci In AGARD Effects of Long-Duration Noise Exposure on Hearing and Health Nov. 1975 2 p (For availability see N76-17788 08-52)

Aviation specialists were exposed daily to high noises and fully protected against hearing damage by ear plugs. The exposed people were divided in two groups of ten subjects, each one exposed to different noisy conditions. One group was exposed to continuous and steady noise of 120 db for 1 hour and 1/2 hour, and the other was exposed to intermittent noise of 80-100 db for 5 hours, with intervals between impulsive bursts of 20 feet, lesting each only a few seconds. The subjective tolerance was good and no disturbance or fatigue reactions appeared at the and of the exposure. Urinary catecholamine excretion was assayed the day before the test (in noiseless place) and the next one at the end of the exposure. Results indicate that no change in catecholamine release occurs upon trained people with hearing fully protected. Author

PHYSIOLOGICAL EFFECTS OF NOISE

Robert W. Cantrell In AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 11 p refs (For availability see N76-17786 08-52)

The effect of noise on the bigghemistry of the body, the cardiovascular system, and the organ systems controlled by the autonomic nervous system are examined. Noise serves as a stressful stimulus which provokes the General Adaption Syndrome, and is one of the several stressful stimuli which activate this syndrome via the hypothalmus to the pituitary which produces ACTH resulting in increased adrenocortical activity. There is considerable evidence to support this concept, and this theory along with recently carefully controlled studies, are reviewed.

Robert T. Camp, Jr., Ben T. Mozo, and James H. Patterson In AGARD Effects of Long Duration Noise Exposure on Hearing and Health Nov. 1975 6 p (For availability see N76-17786 08-52)

The acoustic output of voice communication systems was measured helicopter during training flights. The results of analyses of samples of aircraft voice communication systems noise are examined. Specifically discussed are ear protecting devices (helmets) used to reduce cockpit noise and passenger compartment noise. It is found that the microphones in the helmets emit sound levels which are harmful over a long period

N76-17799 Universitaetsklinikum Essen (West Germany).
PHYSIOLOGICAL RESPONSES DUE TO NOISE
INHABITANTS AROUND MUNICH AMPORT NOISE IN Gerd Jansen In AGARD Effects of Long Duration Noise Exposure

on Hearing and Health Nov. 1975 5 p (For availability see N76-17786 08-52)

Results are examined of an interdisciplinary research study on aircraft noise effects on inhabitants around German airports. A pilot study (around Hamburg sirport) and a main study (around Munich airport) were conducted by acoustical, demographic, social scientific, psychological, physiological and medical sections of scientists. It was found out that, in general, there is no adaptation to aircraft rioise. A linear relation exists between increasing noise stimuli (combined noise, exposure, measure of noise levels, and number of flyovers) and human reactions. A discussion of physiological results leads to the opinion that physiological reactions are more related to sound levels whereas the 'whole reaction' (annoyance, blood pressure etc.) is more related to combined noise exposure measures.

US ARMY MEDICAL IN-FLIGHT EVALUATIONS, 1985-1975

Chester L Ward, Nicholas F Barraca (Brooke Army Med. Center, Ft Sam Houston, Tex.). Robert J. Kreutzmann (Madigan Army Med. Center, Washington). David D. Glick (Army Aeromed. Res. Lab., Fort Rucker, Ala.), and Morris A. Shamah. In AGARD The Use of In-Flight Evaluation for the Assessment of Aircrew Fitness. Feb. 1978, 10 p. refs (For availability see N78-19789, 10-52).

The U.S. Army has recognized that the services of many experienced but medically disqualified aviators can be lost unless a method is established to comprehensively investigate an individual's adeptation and complete espability. Therefore one hundred thirty-two in-flight evaluations for a 10 year period (1985-1974) were reviewed, information from the records and reports reposited at the U.S. Army Aeromedical Center, Fort Rucker, Alabama, was read, extracted and synthesized. Evaluation methods used, plus the results of compiling case classifications and the subsequent medical recommendations for duties involving flying are presented and discussed. Specific categories of individuals presented in detail are lower extremity amputees, 'one-eyed' aviators, and color vision defective aviators. Author

N76-19791 Civil Aeromedical Inst., Oklahoma City, Okla. ACCIDENT EXPERIENCE OF CIVILIAN PILOTS WITH STATIC PHYSICAL DEFECTS

J. Robert Dille and Charles F. Booze. In AGARD. The Use of In-Flight Evaluation for the Assessment of Aircrew Fitness. Feb. 1976. 5 p. refs (For availability see N78-19789. 10-52).

The U.S. Federal Aviation Administration (FAA) is committed to establishment of airman physical standards and certification policies that are as liberal as possible compromising aviation safety. Throught the years, medical flight results, research, and consultant opinions have resulted in relaxation of medical standards and policies and current FAA certification of 4,704 pilots with blindness or absence of one eye. 14,421 who wear contact lenses, 15,779 with deficient color vision, 15,543 with deficient distant vision and smaller, but significant, numbers with paraplegia, deafness, and amputations limitations are placed on flying activities when appropriate. Routine aircraft accident investigations sauk to determine the presence of physical problems in the involved airmen and any probable association of the defect with the accident cause. The FAA experience with these divilian pilots who have static physical defects is examined and accident rates were calculated for several categories of pathology for comparison with the overall accident rates in general aviation activities. Three categories show significant increases in accidents: (1) blindness or absence of one eye, (2) deficient color vision with a waiver, and (3) deficient distant vision. However, these groups reported much higher median flight times than a nonaccident airman population and accident airman without any of the pathology selected for this study. Analyses of available data prove inconclusive but increased exposure may account for most or all of the increased accidents observed for airmen with these three pathologies. None of the accidents was related to the pilots' physical condition in the reports. Statistical biomedical data are given. Author

STRESS AND PSYCHIC FUNCTIONS: OPERATIONS OF
FLIGHT CREWS AND PARATROOPS DURING PARACHUTE
OPERATIONS

Luigi Longo In AGARD The Use of In-Flight Evaluation for

But Mayor

the Assessment of Arrotew Fitness. Feb. 1978 8 p. refs (For availability see N76-19789 10-52)

Observations are presented which were made of the behavior of a considerable number of parachutists and flight crews during prrachute operations. Such operations are marked by a series of phases or pre-arranged maneuvers which involve both the higher processes and simple motor mechanisms. A trained parachute officer and psychiatrist of the Italian Air Force studied the stresses which occur in the various phases and especially the involvement of the higher psychic processes it appears that the emotive-affective complex is especially exposed to operational stress in this situation. Hypotheses are advanced on such issues as these with special reference to the psychological content and to the effect of drill and discipline on stress.

N76-19793 Army Aeromedical Research Lab., Fort Rucker, Ala. COMPARISON OF VISUAL PERFORMANCE OF MONOC-ULAR AND BINOCULAR AVIATORS DURING VFR HELI-COPTER FLIGHT

Thomas L. Frezell and Mark A. Hofmann In AGARD. The Use of in Flight Evaluation for the Assessment of Aircrew Fitness Feb. 1976 9 p. refs (For availability see N76-19789 10-52).

The inflight visual performance of six binocular Army aviators and one monocular Army aviator was assessed during various maneuvers in a JUH-1H helicopter. A comeal reflection technique using both video tapo and 16mm film as a recording medium was employed. Information on the use of 13 visual sectors was provided for a number of maneuvers to include normal takeoffs and landings and hovering maneuvers. The erroraft windscreen was divided into eight sectors while the side windows and ohin bubbles comprise an additional four sectors. The thriteenth visual scotor represents the inside cockpit area. Data presented include percentage of total time spent in each sector, average dwell time per sector transition (permutation) values. Comparison data are provided between the six binocular pilots and the monocular pilot. These data reveal that or many cases there was little difference between binocular and monocular visual scrivity. In addition to the objectively recorded data, information concerning monocular visual cues is presented.

N76-19794 Army Agromedical Research Lab., Fort Rucker, Ala HELICOPTER FLIGHT PERFORMANCE WITH THE AN/PVS-5, NIGHT VISION GOGGLES

Michael G. Sanders, Kunt A. Kimball, Thomas I., Frezell, and Mark A. Hofmann. In AGARD. The Use of In-Flight Evaluation for the Assessment of Alorew Fitness. Feb. 1876. 15 p. rels. [For aveilability see N76-18789 10-52].

Rotary wing flight at night in an instrumented UH-1H with aviators utilizing night vision goggles was studied. These devices restrict field of view, provide monochromatic imagery, and weight, and with the exception of bifocals require manual refocus to gain inside visual capability. These second generation image intensification systems were used during low level and hap-of-theearth flight profiles in addition to various maneuver sets. Three Intensification systems were compared to the unaided eye over these conditions. These systems included 40 deg field of view (FOV), 60 deg FOV and 40 deg FOV with a 30 percent bifocul cut. Over twenty aircraft state variables and aviator control inputs were measured and submitted to analysis. In addition to descriptive and univariate techniques, the data were subjected to a multiple discriminant analysis. The subjects (instructor pilots) also responded to questionneires regarding the preference, training and estimated capabilities of each type of intensification system. The major findings of both the subjective and objective measures are summinarized

IN-FLIGHT LINEAR ACCELERATION AS A MEAN OF VESTIBULAR CREW EVALUATION AND HABITUATION Rudolf J. VonBaungerten /n AGARD The Use of In-Flight Evaluation for the Assessment of Aircrew Fitness Feb. 1978 4 p. refs (For availability see N78-19789 10-52)

Individual differences in susceptibility to motion sickness and in man's ability to habituate to vestibular stimuli was studied. It is proposed that individually oriented programs of vestibular testing (ground based) be supplemented by specific in-flight tests and in-flight habituation trowing for the following reasons: (1) the stimuli which cause vestibular airsiokness in high performance aircraft at the abortest latency are rectilinear accelerations (totilithic-stimuli) of amplitudes, jerkloads and frequencies which cannot be simulated on the ground without enormous technical

difficulties, and (2) the conventional ways of testing for motion sickness on the ground, involving coriolis-effects on rotating chairs, swings, caloric stimulation of the ears and centrifugation, do not simulate closely enough conditions of aircraft flight. It is suggested that special vestibular in-flight test and training regimens be used, based on individual traits. The test and habituation flights should include z-Axis acceleration between 1 and 12 g's, changes of rhythm of such stimulation, and alternation between threshold and sub-threshold maneuvers of opposite direction. Preliminary data obtained in a Lear-jet and in aerobatic light planes are examined and indicate that certain otolithic stimuli are very effective in producing motion sickness, and that habituation can be obtained against such stimuli

EFFECT OF INCREASED ATMOSPHERIC ELECTRICITY ON THE SLOOD ELECTROLITES OF AIRPLANE CREW
Guitekin Caymaz In AGARD The Use of In-Flight Evaluation
for the Assessment of Aircrew Fitness Feb 1978 5 p refs

(For availability see N76-19789 10-52)

Airplane pilots during flights sometimes develop disorientation and fly in wrong directions with accidents resulting. It is proposed that the cause of disorientation or collapse in some of these cases may be the sudden changes in blood electrolites and soldity of the blood produced by increased atmospheric electricity Experiments are described that were made on airplanes and their crews which show that the atmospheric electricity is higher inside the sirplane than outside. Blood samples taken before and after flight show definite changes of addity, electrolites and cholesterol. Atmospheric electricity was measured on a daily basis, and following high voltages, there were always increased amounts of traffic and airplane accidents. The study was conducted by the Turkish Air Force.

SPINAL INJURY AFTER EJECTION [LESIONS VERTE-BRALES APRES EJECTION)

R. Auffret (Lab. de Med. Aerospatiale du Centre d'Essais en Vol de Bretigny sur Orge, France) and R. P. Delahaye (Hopital Militaire Begin, Saint Maide, France) 1975 59 p refs (AGARD-AR-72(FR)) Avail NTIS HC \$4.50 In FRENCH

Statistical data from seven NATO countries dealing with the frequency of fatalities, spinal fractures, and their distribution following ejection from aircraft was presented and analyzed. The relevant anatomical and physiological aspects were reviewed, followed by a discussion on the pathological mechanism of fractures. In most cases, it is difficult to determine whether the spinal fractures take place during the initial ejection or during the subsequent landing. Proper positioning of the pilot on the ejector seat is an essential requirement for a successful ejection. The radiological aspects of spinal fractures were described by distinguishing between stable and unstable fractures. The subsequent treatment and disability period were described. It is recommended that, following any ejection, a radiological examination of the entire spinal column should be completed The strict actitude requirements set by most air forces for combat alloraft pilots ware discussed. COMMON PROBLEMS ENCOUNTERED IN LABORATORY SCREENING OF USAF FLIGHT CREWS FOR LATENT CORONARY ARTERY DISEASE

R. G. Troxler In AGARD. The Role of the Clin. Lab in Aerospace Med. May 1978 11 p refs (For availability see N76-27819 18-52) Copyright.

Laboratory screening to identify men at increased risk for coronary artery disease is discussed. Annual determination of cholesterol and triglyceride levels, monitoring of accuracy and precision by in-house and external quality control, and effects of biological variability are among the factors included. Data are presented showing that separation of diseased from nondiseased population improves with increased laboratory precision. A normal range based on percentiles for 925 USAF male flyers without detectable coronary artery disease is also presented. The limitations of this method of normal ranges are discussed.

APPLICATION OF FLIGHT STRESS SIMULATION TECHNIQUES FOR THE MEDICAL EVALUATION OF AIRCREW PERSONNEL POSSIBILITE DE L'UTILISATION DES MOYENS DE SIMULATION DES AGRESSIONS AERONAUTIQUES POUR L'EXPERTISE MEDICALE DU PERSONNEL NAVIGANT]

J. Demange, R. Auffret, B. Vettes, and J. L. Poirier In AGARD The Role of the Clin. Lab. in Aerospace Med. May 1976 7 p. refs. In FRENCH (For availability see N76-27819 18-52)

The role that may be played by an aerospace medicine laboratory, well equipped with simulation tools such as centrifuges, vibration generators, etc. and measuring tests such as physiologic and psychophysiologic examinations, in the more difficult medical evaluation of aircrew personnel, was described. This is based on the logic that, in borderline cases, a final decision on the modical fitness of pilots for flight status should only be reached after completion of tests that simulate, as realistically as possible, the stresses actually encountered in flight, in addition, such a laboratory is able, by repeating such tests, to objectively obtain longitudinal data on a pilot, to study transient favorable or unfavorable changes, and to observe the long-term effects of aging.

STUDIES ON STRESS IN AVIATION PERSONNEL, ANALY-SIS AND PRESENTATION OF DATA DERIVED FROM A BATTERY OF MEASUREMENTS

C. E. Melton, J. M. McKenzie, J. T. Saldiver, and Martene Hoffmann In AGARD The Role of the Clin. Lab. in Aerospace Med May 1876 6 p. refs (For availability see N76-27819 18-52) Copyright

Determination of stress in aircraft pilots and air traffic controllers is considered. The complexity of the data derived from batteries of measurements of stress is discussed. A method is described in which data related to stress indicators are weighted so that their importance is equivalent. The weighted value are integrated to yield an index, C sub s, which allows a comparative overview of stress in air traffic control facilities. Data so normalized can be presented in graphic form without oversimplification. The method increases the usefulness of stress studies to managers.

The 5-man fire direction center (FDC), common to all Field Artillery batteries, was chosen for study in the laboratory and field to evaluate the impact of environmental and situational stress on the complex performance of highly trained and motivated individuals working together as a team. The working environment of a field FDC was simulated within a hypobaric chamber and a volunteer FDC team from an elite U.S. Army unit was tested using realistic matched combat scenarios. To minimize practice effects, the team was initially given 26 hours of intensified training (ITS). The team was then tested blinded as to the altitude condition for 48 hours at both a control sititude and high sititude; the team rested 22 hours between ITS and control and 48 hours between control and the high altitude conditions. Mission performance during ITS and control was sensitive to disrupted sleap-rest cycles, with errors clustering at times of low arousal At high altitude, performance was less efficient during the first 10 hours; most serious errors involved processing of digits. Over learned FDC skills showed little deterioration even when the men were ill with acute moutain sickness. Compensatory behaviors were evident and technical performance for the last 36 hours at high altitude equalled or exceeded control. Thus communications, psychomotor, and judgement aspects of FDC performance, as well as measures of symptoms, mood, and neuroendonrine response, appear differentially sensitive to psychological atress. hypoxia, and fatigue.

BEHAVIOR OF SOME RESPIRATORY PARAMETERS IN CANDIDATE PILOTS. A COMPARATIVE STUDY BETWEEN TWO DIFFERENT GROUPS EXAMINED AT YEN YEARS INTERVAL

C. A Ramaddi and G. Meineri. In AGARD. The Role of the Clin Lab in Aerospace Med. May 1976. 7 p. refs (For availability see N71: 27819-18-52).

The hypothesis that static respiratory values could undergo a change in the course of time, in the same age groups was studied. A comparison was carried out between two groups of candidate military pilots. The respiratory parameters taken into consideration were vital capacity and time vital capacity. The results show that no significent change took place. It is still deemed advisable to perform periodic checks. The existence of other elements that could exert a certain influence on the parameters studied was established.

J. Colin, J. Damanga, and J. Langlois. In AGARD. The Role of the Clin. Lab. in Aerospace Med. May 1976 12 p. refs. in FRENCH (For availability see N76-27819 18-52) Copyright.

Changes in the electric impedance measured with electrodes on the anterior portion of the thorax, near the descending sorts. were found to be proportional to the volumetric changes of the thoracic vessels in that region investigations of the effect of age on the data obtained with 91 healthy subjects disclosed that the change in the electric impedance are partly caused by changes in the elasticity of the blood vessels. The experimental data was also used to study the systolic volume and heart output Calibration was obtained using 120 simultaneous measurements with the dilution method and electric impedance data on cardiac subjects. The results obtained with healthy subjects are in good agreement with those previously obtained using Fick's method. especially in regards to the effects of age and position. On the other hand, the medicare correlation between the dilution and electric impedance methods with cardiac subjects makes this approach presently impractical clinically ALY vd lannt

N76-27835 Amsterdam Univ (Netherlands) THE INFLUENCE OF ALCOHOL ON SOME VESTIBULAR TESTS

WARNING SYSTEMS IN AIRCRAFT CONSIDERATIONS FOR MILITARY OPERATIONS
D. C. Reader In AGARD 4th Advanged Operational Aviation

Med Course May 1976 3 p. refs (For availability see N76-27846

The principles employed in the design of warning systems in aircraft are presented Visual, auditory, and tactile signals are discussed in detail it is concluded that the concept of visual display combined in a sensory warning system is probably the most efficient method of presenting essential emergency information to the crew. It is further stated that apart from a few specific cases, audio warnings do not have distinct advantages over visual displays

N76-27865 Royal Air Force Inst of Aviation Medicine, Famborough (England). Flight Skills Research Section ADVANCES IN MILITARY COCKPIT DISPLAYS

J. M. Rolfe. /n AGARD. 4th Advanced Operational Aviation Med Course May 1976. 4 p. rafs (For availability see N76-27848

Recent advances in display technology which have taken place in relation to the military cockpit were examined. Emphasis was placed upon providing adequate assessment of information needed by the alrolew in order to perform their task, and from this evolves a display system capable of presenting information in a flexible manner. It is further stated that the most widely used form of display is the cathode my tube which has the required flexibility.

N76-27856 Royal Air Force Inst. of Aviation Medicine. Farnborough (England) MAP DISPLAYS

R M Taylor In AGARD 4th Advanced Operational Aviation Med Course May 1976 4 p refs (For availability see N76-27846

The major types of map displays are distinguished and their functions are described. The principal design parameters are reviewed with particular reference to user requirements and human factors, and an outline is given of current problems of map annotation, display legibility and brightness, radar-map matching and display complexity Author

N76-27857 Royal Air Force Inst. of Aviation Medicine. Farnborough (England).

PHYSIOLOGICAL LIMITATIONS TO HIGH SPEED ESCAPE

David H. Glaister. In AGARD. 4th Advanced Operational Aviation Med Course May 1976 5 p refs (For availability see N76-27846 18.52)

The forces which must be imposed for satisfactory high-speed sjection approach, or even surpass, the limits of human tolerance at several stages in the ejection sequence are: (1) the +Gz acceleration of the ejection seat; (2) the -Gx acceleration due to wind drag. (3) direct (pressure) and indirect (flail) effects of wind blast, (4) other inertial forces (centrifugal, tangential) due to seat instability. (5) opening shock of drogue parachute and main canopy, and. (6) ground impact. Of these forces the first must be increased to achieve tail fin clearance at high speed. the second and third increase with the square of indicated air speed, the fourth increases with sirspeed, and the fifth must be increased if escape is to be successful in the high-speed low-level case. Only the last force is uninfluenced by aircraft speed at ejection and the message is clear - high apped has a major

effect on forces imposed during assisted ascape from aircraft. These forces are considered in relation to the mechanism of injury, incidence of injury, tolerance to injury and in particular, to the influence of air speed at ejection

N76-27858 Royal Air Force Inst of Aviation Medicine. Farnborough (England) PRINCIPLES AND PROBLEMS OF HIGH SPEED EJEC-TION

A J Barwood In AGARD 4th Advanced Operational Aviation Med Course May 1976 4 p (For availability see N76-27846

The principles of ejection are described to recover aircrew uninjured, which is best achieved by the use of as simple an escape system as technically possible. Once the system has been initiated all sequences automatically follow and there is no further action required by the ejectes until he is descending on a fully deployed parachute. The hazards of ejection and the development of the open ejection seat system up to the maximal capability are briefly described. The sequences of ejection on a typical Martin Baker Aircraft escape system are outlined to stress the simplicity, and therefore technical reliability, of this system as used in the majority or service aircraft in the UK Services.

THE PHYSIOLOGY OF HIGH G PROTECTION

B J Lisher In AGARD 4th Advanced Operational Aviation Med Course May 1975 2 p. refs (For availability see N76-27845 18-52)

The introduction of several new combat aircraft which have the structural integrity and the engine power to execute managers. at high levels of acceleration for considerable periods of time reintroduces the concept that certain operations, particularly air to air combat, may be physiologically limited rather than limited by aircraft design parameters. An acceleration level of 8G sustained for 60 seconds has been suggested as a point to which acceleration protection should be aimed, although higher G levels for shorter periods of time can be expected. Two methods of high G protection are presented, one using a reclining seat and the other using immersion of the body in water

PERSONAL THERMAL CONDITIONING

Cratg Saxton In AGARD 4th Advanced Operational Aviation Med Course May 1976 6 p (For availability see N76-27846 18-52)

The inadequacy of cabin conditioning systems in high performance aircraft has resulted in aircraw being exposed to severe heat stress situations within the cockpit environment during certain flight profiles. To alleviate the physiological strain imposed upon the man, methods of thermally conditioning the micro-environment within flying clothing assemblies have been investigated and applied to operational situations. The couling agents used in the personal thermal conditioning role have been air or water. The former has been utilized either as an evaporative agent or convective cooling agent. The relative merits of the different personal conditioning systems are discussed and a case made for the development of a practical liquid-cooled suit system for use in present and future high-performance aircraft

PRESSURISATION AND OXYGEN SYSTEMS. REQUIREMENTS

J. Ernsting In AGARD 4th Advanced Operational Aviation Med. Course May 1976 & p. refs (For availability see N76-27846 18-52)

The considerable interactions between the physiological requirements for cabin pressurization and the relationship between concentration of oxygen and cabin altitude required of oxygen delivery systems for aircrew in flight are explored. Although work performed until 1960 suggested that hypoxia induced by breathing air at altitudes of up to 8,000 feet was acceptable, investigations performed more recently at RAF IAM and elsewhere suggest that the maximum acceptable degree of hypoxia for strorew in flight is that associated with breathing air at 5,000 feet. The incidence of hypoxia due to malfunction of oxygen delivery equipment and of decompression sickness at altitudes above 20,000 feet is such that the maximum cabin altitude in combat singraft should not exceed 20,000 to 22,000 feet. The concentration of dxygen which must be breathed to avoid transient hypoxia on audden failure of a pressure cabin even when 100% oxygen is delivered to the respiratory tract immediately the decompression occurs is generally greater in high differential pressure alroraft than that required to prevent significant hypoxia with the pressure cabin intact. Even in modern combat eircraft this consideration requires a higher than 5,000 feet equivalent breathing mixture at aircraft aititudes greater than 35,000 feet. Author

ABSORPTION, METABOLISM AND EXCRETION OF HYPNOTIC DRUGS

Stephen H. Curry. In AGARD. 4th Advanced Operational Aviation. Med. Course May 1976 7 p refs (For availability see N76-27846

Absorption, metabolism and excretion are the processes which govern the growth and decay of plasma concentrations of all drugs, including hypnotics. Variations in plasma concentrations lead to corresponding variations in effect, although the exact detail of the relation between level and effect is more complex than is implied by this statement. Existing data on absorption, metabolism and excretion for the various hypnotic drugs are of variable detail. Total absorption of oral doses is generally balleved to occur, although when systematically examined, abscription has sometimes been found to be incomplete. Metabolism occurs by a variety of reactions, but only occasionally to pharmacologicallyactive compounds. Excretion is of both unchanged drug and metabulities in bile and urine. These events and processes as they relate to hypnotic drug actions are considered in detail.

COSMIC RADIATION DOSES AT AIRCRAFT ALTITUDES E. W. Fuller. In AGARD. Biophysical Probl. in Aerospace. Dec. 1976. p 3-26. refs (For primary document see. N77-16728. 07-52)

Avail NTIS HC A08/MF A01

The radiological doses associated with cosmic radiation in the sititude bands used by military aircraft are examined. Three altitude bands were studied: 35,000 to 40,000 ft (200g/sq cm) used by subsonic jets, 50,000-85,000 ft (100g/sq cm) for supersonic aircraft operating at about Mach 2 and 38,000 ft (20g/sq cm) for aircraft operating at Mach 3. It was seen that the greater part of the close arises from lightly ionizing radiation and from neutrons of energy up to a few MeV. For these radiations the procedures for converting the data from flux measurements to dose estimates are well established in principle

Gaetano Rotondo In AGARD Recent Experience/Advan. in Aviation Pathol. Dec. 1978 14 p. refs (For primary document see N77-17710 08-52)

Avail: NTIS HC A07/MF A01 Necessity is premised of close collaboration between the specialist in forensic medicine and the flight surgeon, in flying accidents investigation. These accidents are surveyed in their different types, various traumatic mechanisms and possible correlations existing between physic-psychical conditions of flying personnel and genesis of single accidents. Different body lesions, sustained by viotims of flight accidents, are deeply examined They are divided into lesions pertaining to skeleton, internal organs and external toguments; and pathogenetic interpretation of each injuries is discussed. As conclusion, reconstruction of causes and ways of flight accident production is discussed. This can be possibly carried out through the examination of differential characteristics of various traumatic findings of the different types of accidents, considering kinedynamics of the single accident as well as the phase in which the injuries were sustained (precipitation, or explosive decompression with subsequent precipitation, or impact on the ground followed by an explosion or not, or explosion in flight followed by impact, or finally the terminal fire on board with or without inhalation of smoke or toxic gases). From this reconstruction useful elements can be obtained, for the prevention of flight accidents and dependent injuries. Author

THE INTERPERTATION OF PRECENTAGE SATURATION OF CARBON MONOXIDE IN AIRCRAFT-ACCIDENT FATALI-TIES WITH THERMAL INJURY

Joseph M. Ballo and Abel M. Dominguez In AGARO Recent Experience/Advan. in Aviation Pathot. Dec. 1978 8 p refs (For primary document see: N77-17710 08-52) Avail: NTIS HC A07/MF A01

Victims of sircraff-accident fatalities suffering severe thermal traums (as defined by second- or third-degree burns anti/or percent saturation of osrboxyhemoglobin values of 10 or greater) were evaluated. Of 518 cases accessioned from 1988 through 1974, 83 had either sublethal or no physical traums. The mechanism of death in such cases is (1) glottal spasm, bronchosperm, or acute edems of the upper respiratory passage, (2) cardiovascular collapse secondary to vagal inhibition, (3) acute thermal hyperkalemia potentiated by high levels of circulating cateholamines, (4) complete combustion of flammable material by on-board oxygen supplies, producing an intense fire without the production of CO, or (5) poisoning by other toxic products of combustion.

Joseph M. Ballo and Robert R. McMaekin In AGARD Recent Experience/Advan. in Aviation Pathol. Dec. 1976 11 p. refs (For primary document see N77-17710 08-52)

Avail. NTIS HC A07/MF A01

From an ongoing study of over 500 fatally injured crewmembers of U.S military sircreft every year and an analytically oriented research program in which injury patterns were varified by computerized simulation techniques, estimates were prepared of injury correlated with both the magnitude and the direction of the applied decelerative force. When an accurate tabulation of postmortem injuries was correlated with measurements of the path of the aircraft after it struck the ground, the dynamics of impact were deduced. This process was invaluable for accidents that occurred without witnesses or survivors and in which crash damage to flight instruments or the absence of flight-data recorders made calculation of impact kinematics difficult. Skeletal injuries,

particularly vertebral compression fractures, lacerations and contusions of viscers, sortic tears and facerations, and cutaneous contusions caused by complussion of harnesses and seat belts, were important factors in determining the direction and magnitude Of the deceleration vector

HEAD INJURY PATHOLOGY AND ITS CLINICAL, SAFETY AND ADMINISTRATIVE SIGNIFICANCE Stanley C. Knepp and Thomas M. Erhardt. In AGARD. Recent Experience/Advan in Aviation Pathol. Dec. 1976 9 p. refs (For primary document see N77-17710 08-52) Avail NTIS HC A07/MF A01

A review of head traume in war, vahicular accidents, sports. and aviation demonstrated that while the head constitutes roughly 9 percent of the body's weight, surface area and volume, it is implicated in 7 out of 10 body injuries. Head traums causes an unacceptable 1 in 4 deaths and for motorcycling it causes a staggering 1 out of every 2 deaths. It was proposed that examination of head trauma, its coats and the effectiveness of provided protection must apply the analytic tools of epidemiology not only to the injury but to the equipment as well. Prevention requires anticipatory action, based on the knowledge of protective performance history, in order to make the onset or further occurrence of injury unlikely.

FATAL HELICOPTER ACCIDENTS IN THE UNITED KING-

A. J. C. Balfour In AGARD Recent Experience/Advan. In Aviation Pathol. Dec. 1976 8 p (For primary document see N77-17710 08-52)

Avail: NTIS HC A07/MF A01

There were 27 fatal helicopter crashes investigated in the United Kingdom in the years 1956 to 1975; there were 52 deaths and 15 survivors. Of the crashes 25 percent were survivable and produced 15 percent of the casualities and 73 percent of the survivors. There were 44 men killed in the non-survivable accidents and 4 escaped. In the 6 survivable crashes 8 men died: 5 drowned, one died from fire, one died from traumatic asphyxia, and one submarined out of his safety harness. The casualties emphasized the need for further improvements in training and in helicopter crash worthiness, and for the best early rescue facilities that can be provided.

MATHEMATICAL MODELS OF HUMAN PILOT BEHAVIOR Duane T. McRuer (Systems Technol, Inc., (Hawthorne, Calif.) and E. S. Krendel (Pa. Univ.) Jan. 1974 83 p. refs.

(AGARD-AG-188; AGARDograph-188) Avail: NTIS HC \$7.25 Mathematical models of the human pilot are used for analyses of the pilot/vehicle system. Elementary concepts and specific physical examples are used for a step-by-step development of what is known about the human pilot as a dynamic control component. In the process, quasi-linear models for single-loop systems with visual stimuli and multiloop systems with visual stimuli are presented and then extended to cover multiloop, multi-modality situations. Empirical connections between the plict dynamics and pilot ratings are also considered. Nonlinear features of human pilot behavior in adapting to changes in the character of the stimuli are described and tied to the quasi-linear models via the successive organization of perception (SOP) theory, which is reviewed and elaborated. Dual-mode control models needed to describe the pilot's behavior in response to sudden translents are presented, along with pursuit and compensatory elements of the SOP continuum. The current status of mathematical pilot models is shown to gover random, random-appearing, and transient inputs for single- and multi-loop system configurations. A bibliography of applications and a summary of analysis problems

THE OPERATIONAL CONSEQUENCES OF SLEEP DEPRIVA-TION AND SLEEP DEFICIT

Averne C. Johnson (Navy Mad. Neuropsychiatric Res. Unit) and Paul Naixoh (Navy Med. Neuropsychiatric Res. Unit) Jun. 1974

(AGARD-AG-193: AGARDograph-193) Avail: NTIS HC \$5.50 The effects of total sleep loss, partial sleep loss, and sleep stage deprivation are reviewed, with purticular attention to performance decrement and operational consequences. No consistent or uniform performance decrement was found in operation studies within the 36 to 48 hour range of total sleep loss most likely to be experienced by aircrew personnel, even though isboratory studies identified decrement on certain types of tasks. Physiological changes are minimal during moderate sleep loss, but mood changes are clearly noticeable. The most likely sleep problems for aircraw members are those associated with disruption of aleap-wakefulness cycles and partial sleep loss. Consistent performance decrement is difficult to find, but marked

increase in fatigue is a common influence on performance, and it interacts with other stressors to enhance the stress-induced physiological responses. Deprivation of sleep stage rapid eye movement (REM) or sleep stage four produces no behavioral changes supportive of earlier beliefs that these two stages. especially stage REM, are necessary for effective waking behavior Author

Harry M. Hughes, Bryce O. Hartman, Raul Garcia, and Paul Lozano In AGARD Simulation and Study of High Workload Operations Oct. 1974 14 p (For availability see N75-12587 03.83)

Alterew workload can be studied at many different levels of detail. In the most general sense, it is a function of the total workload impose upon a unit in relation to the number of urews in that unit. An eirlift system simulation program has been designed using this global approach and a number of simulation studies have been performed. Outcomes in terms of systems effectiveness measures, crew workload, and crew welfare measures will be presented.

N75-12589 National Aerospace Lab., Amsterdam (Netherlands). A SIMULATOR STUDY TO INVESTIGATE HUMAN OPERA-TOR WORKLOAD

P. H. Wewerlinks and J. Smit In AGARD Simulation and Study of High Workload Operations Oct. 1974 6 p. refs (For availability see N75-12587 03-53)

Human response characteristics in control situations of widely varying difficulty were studied. The experiment was simed at a better understanding of the human operator limitations in terms of control effort as included in the optimal control model. Based on the experimental results a control effort index is presented. The predicted control affort correlates excellently with subjective ratings and seems to have a useful generality. Author

LABORATORY RESEARCH INTO HUMAN INFORMATION PROCESSING

Jo H. F. Huddleston In AGARD Simulation and Study of High Workload Operations Oct. 1974 3 p (For availability see N75-12587 03-53)

Pliot workload can be expressed as the coping with two main clusters of problem. One cluster is agulpment based and theoretically amenable to physical modelling, even replacement. The other cluster is emphatically to do with humanity; to do with those elusive personal gambles on which life is felt to depend. Pilot workload might be the maintenance of a mental model encompassing these two kinds of time varying input; the continued provision of a mental solution for two sources of uncertain problem. Respectable transfer function work considers varied inputs, monitor outputs, and debate black box contents with a rare freedom.

J. M. Rulfs, J. W. Chappelow, R. L. Evans, S. J. E. Lindsay, and A. C. Browning (RAE) In AGARD Simulation and Study of High Workload Operations Cot. 1974 13 p. rafs (For availability see N75-12587 03-53)

A flight instrument trainer, resembling a twin jet communications aircraft, was used to evaluate questionnairs, performance and activity analysis measures of pilot workload. Attempts were made to distinguish between the physics", perceptual and mental components of workload. For this purpose three flight plans were devised, of approximately equal duration, differing markedly with respect to the three above components. Six professional pilots flew each flight plan and after landing completed questionnaires to assess the workload levels and the task content. During the flinhts video recordings were made of the pilot's manual and occumunication activity. From the measures it was possible to obtain significantly different results relating to the different flight plans. These results were capable of distinguishing between the three components of workload represented in the

N75-12592 Royal Air Force Inst. of Aviation Medicine, Farnborough (Inniand) A FLIGHT IMPLATOR STUDY OF MISSILE CONTROL PERFORMANCE AS A FUNCTION OF CONCURRENT WORKLOAD

K. G. G. Corkindale In I' with Simulation and Study of High Workload Operations Oct. 1974 6 p refs (For availability see N75-12587 03-53)

Eight pilots took part in a part task simulation of the delivery of a stand-off air-to-surface guided we will not save k phase of a sortie was simulated. This phase lasted some 3 minutes and included a low level run to the weapon release area, weapon release, target detection on the TV monitor display and the siming of the missile at the "arcs. Four levels of workload were studied. The results showed that: (1) performance at the missile control was degraded by increases in gonourrent workload; and (2) manual flight control and auto-pilot monitoring were adversely affected by concurrent missile control tasks.

BIMULATION OF HIGH WORKLOAD OPERATIONS .A AIR

TO AIR COMBAT F. M. Holden, D. B. Rogers, and C. R. Replogle In AGARD Simulation and Study of High Workload Operations Co. 1974 4 p refs (For availability see N75-12587 03-83,

Workload measurements for the study and analysis of human performance are analyzed to provide effectiveness versus design data with specific examples from air to air combat man-in-the-loop simulations. The report concludes with a discussion of man-in-theloop simulation as a technique for system specific human performance data and as a source for the data required to develop general methods and techniques for aredicting the performance of manned weapon systems.

N75-12594 Dunlap and Associates, Inc., la Jolla, Calif. PILOT LANDING PERFORMANCE UNDER HIGH WORK-LOAD CONDITIONS

C. A. Brictson In AGARD Simulation and Study of High Workload Operations Oct. 1974 10 p. refs (For availability see N75-12587

A longitudinal study of pilot carrier landing performance was conducted to describe the influence of prolonged operations on pilot performance. A landing performance criterion previously validated in a fleet environment was used to measure and compare pilot and squadron performance variations over time. Three levels of cumulative workload were defined to evaluate concomitant changes in performance associated with each workload. Pilot landing performance improved over time with more improvement found in night performance than day. The influence of practice on carrier landings is discussed in relation to high cumulative workload. The performance criterion was used to identify potential night pilots on the basis of landing proficiency. High and low proficiency pilots also were identified and diagnostic training information provided.

EMOTIONAL AND BIOCHEMICAL EFFECTS OF HIGH WORK-LOAD

William B. McHugh, Paul Naitoh, and C. A. Briotson (Dunlap and Associates, Inc., La Jolla, Calif.) In AGARD Simulation and Study of High Workload Operations, Oct. 1974, 9 p. refs. (For ava ability see N75-12587 03-53)

A preliminary longitudinal multifactorial study of the interrelationships of blochemical, mood, biographical factors and landing performance under high work load conditions has been carried out with U. S. Naval Aviators. Levels of serum cholesterol, serum uric acid, blood lactate, pyruvate, and mood assessments were made during periods of non-flying activity and during periods of increased cumulative work load. Urio acid values fell during moderate cumulative work load, and cholesterol values fell during high cumulative work load. Increased variability of pyruvate and lactate were noted with increased cumulative work load. Increased cumulative work load did not affect emotions or performance but altered mood association patterns and altered the relationships of mood and performance. Experience was correlated with performance under zero cumulative work load conditions. Emotion correlated with performance under high cumulative work load conditions. Author

N75-12599 Duniap and Associates, Inc., la Jolla, Calif. PREDICTION OF PILOT PERFORMANCE: BIOCHEMICAL AND SLEEP-MOOD CORRELATES UNDER HIGH WORK-LOAD CONDITIONS

C. A. Brictson, W. B. McHugh (Navy Med. Neuropsychiatric Res. Unit), and P. Naitoh (Navy Med. Neuropsychiatric Res. Unit). In AGARD Simulation and Study of High Workload Operations
Oct. 1974 10 p. refs (For availability ses N75-12597 03-53)
A preliminary longitudinal study of the factors affecting the

carrier landing performance of naval aviators under high workload conditions has been carried out. Using stepwise multiple regression techniques, a substantial portion of the variability in landing performance could be accounted for by six factors under zero cumulative workload conditions and by seven factors under moderate cumulative workload conditions. High cumulative workload conditions sharply reduced predictive ability. Although specific aircraft experience and total flight experience were important predictors of average landing performance, blood blochemical levels and emotional states had significant predictive ability. Sleep patterns relate strongly to performence. The factors that determine landing performance change as cumulative as workload increases.

LONG RANGE AIR-TO-AIR REFUELLING: A STUDY OF DUTY AND SLEEP PATTERNS

N. H. Mills and A. N. Nicholson (RAF Inst. of Aviation Med.) In AGARD Simulation and Study of High Workload Operations Oct. 1974 9 p refs (For availability see N75-12587 03-53)

The cleep patterns of ground draw, pilots and tanker craws involved in a long range air-to-air refuelling mission have been related to their duty hours. During such complex operations workload may vary considerably and the demands placed on some aircrew may be very high. It is suggested that the duty hours demanded of individual aircrew should be related to their overall workload. In this way it may be possible to maintain an acceptable sleep pattern in all aircraw and ensure that no individual pilot or grew member is subjected to excessive duty hours.

HIGH WORKLOAD TASKS OF AIRCREW IN THE TACTICAL STRIKE, ATTACK AND RECONNAISSANCE ROLES F. TerBreak In AGARD Simulation and Study of High Workload Operations Oct, 1974 3 p (For availability see N75-12587

High workload tasks are outlined for aircraw performing three distinct tactical roles, namely the strike, the attack and the reconnaissance roles. The total mission is covered, which is from the time the pilot receives his orders until the debriefing following the flight has been completed. At the same differences between each role, as related to workload, are printed out so that a fairly realistic comparison can be made as to the workload of each category. Author

N75-12802 Royal Air Force, Binbrook (England). THE AIR DEFENCE ROLE

J. Hutchinson In AGARD Simulation and Study of High Workload Operations Oct. 1974 5 p (For availability see N75-12587 03-53)

In considering the workload involved in the air defense role, it is important to be clear as to the dimensions of the subject. On the one hand, any air defense situation will pose a problem which can be defined in absolute mathematical terms, and whose solution implies a certain degree of effort. The assence of air defense is that the intruder will set about making the defender's task as difficult as possible; the tactics he adopts, in addition to making the problem less tractable, may also reduce, through stress, fatigue, feer or soveral more factors the ability of the air defense crew to solve the problem. The perceived workload feding the craws whose ability is thus impaired may prove to be beyond their capability. Pilots need training against all possible threats from supersonic air launched missiles at high level, through high subsonic bomber penetrations at low level, to air combat manoauvring against fighter-type alroraft. This range of possibilities includes herd-on, beam and rear attacks with missiles, guns or both, pressed home either semi-automatically using electronically computed steering information, or visual information. N75-12603 School of Aerospace Medicine, Brooks AFB, Tex. PHYSIOLOGICAL COSTS OF EXTENDED AIRSORNE COMMAND AND CONTROL OPERATIONS

Ralph R. Bollinger, Robert D. ODonnell, and Bryce O. Hartman In AGARD Simulation and Study of High Workload Operations Oct. 1974 9 p ref (For availability see N75-12587 03-53)

During Exercise Night Star the personnel of the National Emergency Airborne Command Post successfully documented their ability to maintain a continuous airborne siert for an extended period. Biomedical evaluation showed that performance was maintained by the mission teams, flight crews, and ground support personnel. When significant fatigue did occur, whether in flight or on the ground, it developed near the beginning of the exercise. The only cases of marked or persistent fatigue were seen in those groups whose day/night, work/rest cycles were shifted and can be attributed in major part to the resulting sleep loss. However, all groups appeared to adapt to their new work schedules as the exercise progressed.

DEFINITION AND MEASUREMENT OF PERCEPTUAL AND MENTAL WORKLOAD IN AIRCREWS AND OPERATORS OF AIR FORCE WEAPON SYSTEMS, A STATUS REPORT Siegfried J. Gerathewohl In AGARD Higher Mental Functioning in Operational Environments Apr. 1976 7 p. refs (For availability see N76-25782 16-53)

The determination of pilot and aircrew workload using psychological, physiological, and operational criteria has yielded valuable results. Methods used in civil aviation can be applied with appropriate modifications to military problems. However, workload measurements associated with highly complex and demanding conditions are still difficult. Data are not available from actual combat missions. The results obtained by simulation are promising and may be improved by the standardization of methods and the application of statistical approaches and mathematical models.

N76-25784 School of Aerospace Medicine, Brooks AFB, Tex. THE CORNELATIONAL STRUCTURE OF TRADITIONAL TASK MEASURES AND ENGINEERING ANALOGUES OF PERFORMANCE IN THE COGNITIVE DOMAIN

Richard C. McNee, Richard A. Albanese, William G. Jackson, William F. Storm, and Bryce O. Hartman In AGARD Higher Mental Functioning in Operational Environments Apr. 1976 6 p refs (For availability see N76-25782 16-53)

Standard performance measures from a traditional battery of tasks (the Neptune battery) were compared with simulated antialroraft gunnery activities under reveral configurations. These measures were found to correlate only to a moderate degree, with the highest canonical correlation between the two sets being 72 Preliminary modeling of the subject reactions on the simulation, a compensatory tracking task, has been accomplished using control theory methods. A tuntative conclusion from this work is that the transfer functions associated with random inputs are reasonable to use for this compensatory tracking task, which involves both deterministic and random inputs.

N76-25788 School of Aerospace Medicine, Brooks AFB. Tex. THE HUMAN AS AN ADAPTIVE CONTROLLER

Richard A. Albanese, Richard C. McNee, Edward J. Engelken.
Peter H. Henry, and Bryce O. Hartman In AGARD Higher
Mental Functioning in Operational Environments. Apr. 1976
8 p. rols (For availability see N76-25782 16-53)

During flight, aircrew members often function as subsystems in feedback control loops. In perticular, visual tracking tasks have been studied for many years. For these tasks, it has been observed that the human elters his control actions when the device to be controlled, or when the bandwidth of the signal to be tracked, is changed. Thus, the human operator appears to bin an adaptive controller. This article reviews the adaptive nature of man's control function using previously published data, and introduces information theory metrics which show a regularity in these data. Also, new data obtained from twelve subjects flying simulator while under the influence of orally administered 190 proof ethyl alcohol (0.0.0.3.0.8, and 0.9 gms/kg body weight) are presented. These results are related to provious studies, using both control and information theory metrics.

N76-25789 Civil Aeromedical Inst., Oklahoma City, Okla Aeronautical Center ASSESSMENT OF PERCEPTUAL AND MENTAL PERFORM-ANCE IN CIVIL AVIATION PERSONNEL.

the state of the s

Siegfried J. Gerathewohl (FAA, Washington, D. C.), W. Dean Chiles, and Richard I Thackray In AGARD Higher Mental Functioning in Operational Environments Apr. 1976 4 p. rofs (For availability see N76-25782 10-53)

A series of experiments were conducted in order to study functions of relevance to aircrew, pilot, and ATC performance They concerned the assessment of montal functions and complex performance on single operators and five man crews while monitoring static and dynamic processes, of perceptual motor tracking ability, as well as group problem solving. Operator proficiency was measured at various levels of demand induced by the simultaneous performance of different combinations of tasks, requiring the exercise of psychological and mental processes. It was found that multiple task performance varied significantly as a function of information input and group interaction. Substantial correlations were obtained between perceptual motor type problem solving and mental ability tests. Moreover, the results obtained from two tracking tasks suggest that a central process exerts a regulatory influence on a variety of physiological variables during increased attention demand and, furthermore, a correlation exists between the ability to austein attention and personality characteristics of the operator.

EMOTIONAL STRESS AND FLYING EFFICIENCY

L. R. C. Haward In AGARD Higher Mental Functioning in Operational Environments Apr. 1976 5 p refs (For availability see N76-25782 16-53)

A comparative study of the effects of emotional and intellectual stress upon flying performance is described. Ten pilots with self-confessed emotional problems, but certified medically fit to fly were matched approximately for age and flying experience with ten pilots confessing to no emotional problems. Emotional stress was induced by a clinical abreactive technique and measured in terms of psychophysiological concomitants. Intellectual stress was induced by the PASAT technique which is an automated numerical task designed to produce mental overload. Flying skill was measured in the presence and absence of both types of stress separately by means of a crossover design. The results show significant differences in flying performance between the two groups and between the two types of stress. It is demonstrated that intellectual stress produces impaired flying skill which is predictable both in degree and duration, whereas emotional stress produces substantially more severe but fluctuating degrees of impairment of unpredictable duration. The use of a psychometric technique using personal keywords and physiological monitoring clearly differentiates the two groups of pilots and indicates the origins of emotional stress. Its possible use for screening aircraft captains before important missions is examined. Author

THE EFFECTS OF TWO STRESSORS ON TRADITIONAL
AND ENGINEERING ANALOGUES OF COGNITIVE
FUNCTIONING

William F. Storm, Richard C. McNes, Richard A. Albanese, and Bryce O. Hartman In AGARD Higher Mental Functioning in Operational Environments Apr 1976 12 p refs (For availability see N78-25782 18-53)

The sensitivities to stress of traditional psychometric measures and human operator technology engineering parameters were compared in two experiments. In the first study, the effects of mild (8,000 ft) and moderate (15,000 ft) hypoxia were assessed. In the second study, standby alert duty was simulated. Systematic comparison was made between performance following sudden awakening and performance following enforced wakefulness. A battery of tasks emphasizing cognitive processes generated traditional performance measures. Psychomotor functions involving vigilance, problem solving, short term memory, and compensatory tracking were exercised. In addition, a two dimensional tracking task provided traditional task measures and human operator engineering parameters. The properties of the task were systematically varied and models developed for each condition. Both the traditional task measures and the HOT model parameters were analyzed for changes suggestive of alterations in cognitive functioning. The data suggest significant influences of both stressors on cognitive functioning. Conventional performance measures from the HOT task were more sensitive to the stress effects than the traditional task battery. Author

STANDARDISATION OF IMPACT TESTING OF PROTEC-TIVE HELMETS A Working Group Report

D. H. Glaister, ed. Feb. 1974 14 p. refs (AGARD-R-629) Avail: NTIS HC \$3.25

1900年1900年

Standardization of biodynamic impact testing on aircrew helmets is considered. A classification of currently used test procedures is attempted and a compromise approach is proposed which could form the basis for agreement within the NATO membership. In addition to impact protection, penetration resistance and helmet retention, it specifies requirements for blast protection, maximum all-up weight and location of helmet's center of gravity.

N77-12708 Advisory Group for Aerospace Research and Development, Peris (France). VISUAL AIDS AND EYE PROTECTION FOR THE AVIATOR Thomas J. Tredict (School of Aerospace Medicine, Brooks AFB. Tex.) Oct. 1978 89 p Presented at the Aerospace Med. Panel Specialist Meeting. Copenhagen, 5-9 Apr. 1976 (AGARD-CP-191: ISBN-92-835-0177-2) Avail: NTIS HC AOB/MF AO1

information concerning visual aids and eye protective devices used by the eviator is discussed. Among the topics considered were: protection from retinal burns and flash blindness due to stomic flash; vision with the AN/PVS-5 night vision goggle; in-flight evaluation of optically stabilized target acquisition devices: and the correction of presbyopia. For individual titles, see N77-12709 through N77-12717.

INTEGRATION OF AVIATORS EYE PROTECTION AND VISUAL AIDS

Gloria T. Chisum and Phyllis E. Morway In AGARD Visual Aids and Eye Protection for the Avistor Oct 1978 p 7 (For primary document see N77-12708 03-54) Avail: NTIS HC A05/MF A01

Recent technological developments have resulted in additional functions being assigned to the halmet and visor. The additional functions range from static aids for distant vision to dynamic displays of information for use in weapon control and guidance. and siroraft management and situational information. Basic requirements for the protective equipment were established. The expanded functions for the protective equipment require that modifications be made in the equipment configuration. The modifications must be accomplished without sacrificing the basic functions of protection. Accomplishment of these two goals requires cooperation between the display designers and crew equipment specialists.

VISION WITH THE AN/PVS-6 NIGHT VISION GOGGLE Roger W. Wiley and Frank F. Holly In AGARD Visual Alds and Eye Protection for the Aviator Oct. 1976 p 12 refs (For primary document sea N77-12708 03-54)

AVAIL NTIS HC A05/MF A01

Results are presented from a series of experiments in which visual performance using the AN/PVS-5 night vision goggle was measured. Visual modulation transfer functions of the man-goggle system were determined and compared to results obtained with unaided viewing. The man-goggle system performance was superior to unaided visual performance at average target luminances equivalent to 5% and 25% moon illuminances. A+ a target luminance equilivalent to a full moon illuminance, unaided visual performance was superior at higher spatial frequencies, while remaining poorer at the lower spatial frequencies. Using a modified Howard-Dolman apparatus, it was determined that the stereoscopic threshold was degraded with the man-goggle system. Field measurements of relative depth discrimination using all available visual cues showed that performance of the man poggle system was statistically equivalent to unaided phototopic visual performance at intermediate viewing distances, but was inferior to unaided viewing at distances of 500 feet or Author

IN-FLIGHT EVALUATION OF HAND-HELD OPTICALLY STABILIZED TARGET ACQUISITION DEVICES

Devid D. Glick In AGARD Visual Aids and Eye Protection for the Aviator Oct. 1976 p 13 (For primary document see

N77-12708 03-54)

Avail: NTIS HC A05/MF A01

Several target acquisition devices are compared in-flight. Considering size, weight, complexity, and performance in an in-flight visual acuity task, one of the devices looked promising. A group of twenty-nine subjects used a single device in a scout helicopter flight scenario. The device produced motion sickness and the experimental plan was designed to assess this as well as visual acuity in flight. The subjects flew the scenario first with the unsided eye and then with the device in both a stabilized and unstabilized (caged) mode. The latter two flights were counterbalanced across subjects. Following the flight phase, the subjects were given a series of tests to evaluate individual susceptibility to motion sickness. Performance in the visual adulty tesk was significantly correlated with the sirsickness rating of an on-board experimenter; however, there was no significant difference between the magnitude of the symptoms observed when the device was stabilized and the magnitude when caged.

N75-16239 Norwegian Defence Research Establishment, Kjeller. OPTIMIZATION

Yngwar Lundh In AGARD Principles of Avionics Computer Systems Dec. 1974 p 42-45 (For availability see N75-16236 07-59)

An avionics computer system, as well as all other engineering jobs, nequires optimization. This optimization process may be different depending on whether the systems designer or the computer designer does the job. For this discussion it was assumed that the solution was not constrained by limited choices of standard sizes, shapes and forms, or by choices made by someone else, past history or had fortune. Some management considerations are briefly discussed. Important technical parameters such as: logic speed, computing speed, memory capacity, communication capacity, survivability, modularity, physical parameters, and

programming complexity are briefly described. Some important tradeoffs which are useful to know when seeking a way out of the multitude of possible configurations which a computer based system may be given are also identified.

AVIONICS SYSTEM ARCHITECTURE

R. E. Wright In AGARD Principles of Avionics Computer Systems
Dec. 1974 p 64-87 refs (For availability see N75-16236
07-59)

The system architect's task is to define and combine a set of hardware components to form a system whose aggregate behavior will meet the operational requirement for the system. Most avionic systems start with an operational requirement specified by a user or airframe manufacturer. During the short history of aviation there has been a growth of such operational needs which have presented problems requiring technical solutions. The avionic system derives much from the general development in system engineering, but is subject to particular operational requirements, physical environments, and physical constraints which together justify a somewhat specialized approach. Bome of the problems and techniques involved are briefly described and discussed.

N75-18242 Seienia S.p.A., Rome (Italy). DEFINING THE PROBLEM AND SPECIFYING THE RE-QUIREMENT

Silvio Bosso and Rodolfo Gamberale In AGARD Principles of Avionics Computer Systems Dec. 1974 p 85-118 (For availability see N75-16236 07-59)

This discussion deals with the functional requirements of computer system and aims at the definition of a methodology for deriving them from the knowledge of the tasks to be performed. The nonsiderations presented may be applied both to determine the suitability of a certain computer architecture and to compare different computers against a given application. The treatment starts with a brief survey of typical tasks of an avionic system, from which a sample is taken to be further analyzed as an example. Computer tasks are enalyzed, also with the aid of examples, in order to show how the computer requirements can be arrived at.

MONITORING AND CONTROL OF AEROSPACE VEHICLE PROPULSION

E. S. Eccles In AGARD Principles of Avionics Computer Systems Dec. 1974 p 119-142 refs (For availability see N75-16236 07-59)
Avail: NTIS

The application of digital computer systems to the design of systems for monitoring and control of the propulsion of serospace vehicles is discussed. The general context is related to commercial operation of vehicles using airbreathing engines. This limitation permits concentration of attention on the systems problem and removes the need for any extensive discussion of powerplant characteristics. The restriction is not serious in terms of broad powerplant characteristics. The basic fustures of control requirements are common to all plants using chemical energy sources and combustion for energy conversion. There are strong conceptual similarities, for instance, between throttlesble rocket motors and augmented (reheated) gas turbine powerplants. Time

constants and thrust levels differ but the basic problems of mixture control via independent fuel and oxident flow control and their pumping (in the genural sense) remain the same. The plant control details will be less relevant to systems using hypergolic fuels and nuclear or electric propulsion. In the same way, the operational criteria will be similar for vehicles which, in themselves, are as different as the space shuttle and STOL feeder liner systems. Commercial and military operational criteria elso have many analogous, if not entirely homologous, features. Similar design trade-offs are involved for both types of organizational structure and mission objectives. The discussion identifies the basic principles involved and enables read-across to other types of operation and to other svionics systems disciplines. Author

MAH-MACHINE INTERFACE

E. Keonlien In Ita Principles of Avionics Computer Systems Dec. 1974 p 143-149 (For availability see N75-16236 07-89)

As the complexity of serospace systems grown, the requirement for augmenting, expending and simplifying crew control capabilities becomes more demanding. The man-machine interface, which essentially is a problem of exchanging data between the system and the human has become more quotal for the operation of modern serospace systems. To cope with this problem is new class of information proceeding systems (serospace computers, multiprocessors, multiplexers), control systems and displays have been developed, and the trand toward greater integration is realized. As a consequence, the degree of pilot/operator involvement with the machine has increased in scope and complexity. Some basic elements of the man-machine interface optimization process and its relations to the total evionics system design are briefly reviewed. Author

N75-16245 Advisory Group for Aerospace Research and Development, Paris (France).

NOVEL DEVICES AND TECHNIQUES

E. Kaonjian *In its* Principles of Avionics Computer Systems Dec. 1974 p 150-162 refs (For availability see N75-16236 07-88)

Considerable advances have been made over the whole range of evicinic devices and techniques which have been finding their way into evicinics systems, making them more effective in terms of reliability and operational capability. These are coupled with simplicity and lower cost for maintenance and ownership. This process has been accelerated particularly by the rapid progress in microelectronics, with its far reaching consequences especially for future evicinic computer systems. Some advanced devices and technologies still in development are reviewed, which, when matured, could further improve the effectiveness of evicinic computer systems.

SPECIFYING THE REQUIREMENTS

A. L. Freedman In AGARD Principles of Avionics Computer Systems Dec. 1874 p 183-178 (For availability see N76-18236 07-53)

A four step procedure is described for deriving the specification of an avionice computer system as a whole. Such a specification makes it possible to decide first of all whether to go shead with the system, and secondly if the decision is taken to go shead, to eliminate the main sources of the troubles which have plagued these projects in the past. The procedure stems directly from the definition of a real time system as a tool to seelet in performing a given activity. The activity may be the control of interceptor sincreft or the control of the systems on board an aircraft. Techniques used to design an optimum system to meet the specification are briefly covered.

REDUCED SIZE OPTIMAL CONTROL LAWS

P. Bernhard (IRIA, Resquencount) In its Real Time Computer Based Systems Dec. 1974 6 p refs (For availability see N75-16257 07-62)

The problem considered is that of reducing the number of state variables fed back in the optimal control of a linear plant with quadratic performance index. A classical approach is discussed, where the state variables, or their combinations, to be fed back are chosen a priori. A new approach is proposed where we look for those state variables (or combinations of) that can be ignored. The two are compared and turn out to have very different properties. It is argued that the new method is more significative, less hazardous, and far simpler to carry out.

N75-16261 Texas Instruments, Inc., Huntsville, Ala.
A PROCESS DESIGN SYSTEM FOR LARGE REAL TIME SYSTEMS

Author

Roger R. Bate In AGARD Real Time Computer Based Systems Dec. 1974 8 p refs (For availability see N75-16257 07-62) (Contract DAHC60-72-C-0186)

A process is designed from the top down in a structured programming known as the Process Design Language (PDL). Each level of design consists of references to modules which are defined later at the next lower level of design. Undefined modules at any stage are simulated by simple models to permit execution of the system on a computer. In this way the high level logical structure is varified before expensive detailed voding at lower levels is accomplished, and modules can be tested within a realistic environment. The Process Design System (PDS) provides translator, library management, and simulator construction facilities which relieve the process designer of most of the housekeeping chores associated with configuration control of a large system under evolutionary design.

N75-18262 Royal Military Coll. of Science, Shrivenham (England). REAL TIME OPERATING SYSTEMS

K. L. Hunt In AGARD Real Time Computer Based Systems Dec. 1974 11 p refs (For evailability see N75-18257 07-82)

The development of standard approaches to the design of operating systems is explored. Two systems currently under development or in use illustrate at least a trend to a standard approach. The relevance of work of a more formal nature to the design of operating systems is discussed in the light of recent work on evnehronizing secuences.

AN EXERCISE IN MULTI-PROCESSOR OPERATING-SYSTEM DESIGN

R. S. Newton In AGARD Real Time Computer Based Systems Dec. 1974 9 p refs (For availability see N75-16257 07-62)

Design concepts and structuring of a multiprocessor general purpose operating system are discussed, and those features of the operating system peculiar to multiprocessing are identified.

N75-16265 Royal Rader Establishment, Malvern (England), MASCOT: A MODULAR APPROACH TO SYSTEM CON-STRUCTION OPERATION AND TEST

K. Jackson and H. R. Simpson (Royal Air Force, Leeming, Engl.) In AGARD Real Time Computer Based Systems Dec. 1974 18 p refs (For availability see N75-16257 07-62)

The MASCOT approach has formalized a method for dealing with the interconnection and intercommunication between loosely coupled programs i.e. programs which interact in a manner other than by direct call. To this end, some basic types of modules have been defined which are independent even after compilation. These modules may be connected together to construct subsystems which interface with each other by user defined channels. This construction facility is supported by some basic software which allows software synchronization both within subsystems and between subsystems to ensure an orderly and sustained flow of data through the system. To back up the paper study, the majority of the key features have been implemented using Coral 56 on a Marconi Myriad computer.

A REAL-TIME PROGRAM SYSTEM FOR CONTROLLING A PHASED ARRAY RADAR

Heinz Knetsch In AGARD Real Time Computer Based Systems Dec. 1974 10 p (For evallability see N75-16257 07-62) The software of an experimental radar system is described

that is equipped with a planer phased array antenna and two linear phased array antennad. The planar antenna is used as a primary radar antenna while the two orthogonally arranged linear arrays serve as secondary radar antennas. To operate the experimental radar system it is necessary to have a software system for radar process control and evaluation of the air situation. This software system consists of a series of relatively independent process control programs whose execution is initiated by a superordinate control program under real time conditions. A priority and time slice control in the executive program ensures real time operation. The user programs are complemented by input/output programs each of which controls and supervises an individual device connected to the system. The executive program supervises all events occurring during the process and initiates the required activities.

N75-15267 Naval Electronics Lab. Center, San Diego, Calif. THE CS-4 HIGH LEVEL LANGUAGE AND ITS USE IN REAL TIME SYSTEMS

Warren E. Loper and James S. Miller (Intermetrics, Inc.) In

AGARD Rest Time Computer Based Systems Dec. 1974 11 μ refs (For availability see N75-16257 07-62)

The All Applications Digital Computer (AADC) program is used in the development of a modular computer designed to be assembled from off-the-shelf, large scale integrated (LSI) silicon wafer and magnetic thin film building blocks. From these components can be configured a simple minicomputer, or a large multiprocesor, or anything in between. Exploitations of the architecture of machines such as the AADC require the supporting exploitations of the state-of-the-art of computer programming languages and their use in the development of reusable program modules in the construction of large systems. In an attempt to reduce the high cost of software, CS-4 is being designed to meet this requirement.

N75-16266 Smiths Industries Ltd., Sishope Cleeve (England), COMPACT INTERPRETERS: THEIR IMPLICATIONS ON SOFTWARE AND HARDWARE DESIGN

K. A. Helps In AGARD Rest Time Computer Based Systems Dec. 1974 10 p refs (For availability see N75-16257 07-62)

There is a place in avionics real time systems for programs to be stored in compact code and executed by interpretation. Compact interpretable code is here used to mean code designed to require near-minimum storage. Substantially smaller storage is required for compact code than for normal code as produced by an efficient compiler or assembler. Typically the compression ratio is .5 to .7 and an overhead of a few hundred words for the interpretable are code is a rise in execution time. The use of compact interpretable code is every attractive in some avionics applications on storage considerations alone, but its use has repercussions on other areas of the digital systems design, particularly in improving legibility and maintainability of software and in promoting portability. Compact interpretation is a software analogue of microprogramming.

A LANGUAGE FOR THE SPECIFICATION OF REAL-TIME COMPUTER-BASED SYSTEMS

D. M. Belaton and O. E. Morgan In AGARD Real Time Computer Based Systems Dec. 1974 13 p refs (For availability see N75-16257 07-62)

Current methods of conveying the apecification of real time computer based systems rely heavily on natural language as the medium for communication and agreement between customer and contractor. Misinterpretation and ambiguities are easily introduced if statements are made in natural language however and the cost of realification can be high both in moretary and time terms. The initial specification is presented for a formal language which has been developed to convey system specification information. The language forces the writer to emphasize the hierarchical nature of the system and thus encourages a logical and progressive flow of information. The resulting specification serves a dual purpose as the same text can provide both an overview of the system and a detailed specification of every sub-unit.

FAST INTENT RECOGNITION SYSTEM (FIRST)

S. C. Schroeder and L. E. Vaughn In AGARD Real Time Computer Based Systems Dec. 1974 13 p (For availability see N75-16257 07-82)

The design of an APL language computer for use in command and control systems is investigated. The computer is divided

into four functional units. The major innevation is the unit which determines, at execution time, the optimum execution code for erray processing statements. This code is later executed by another unit specifically designed for array operand expressions. The design is currently being avaluated using an emulator written for an APL, time sharing system. The evaluation shows a distinct cost/performance advantage over both a naive approach and a conventional computer system. In addition, use of this computer in an interactive command and control system or real time aviants application will greatly reduce software development and infegration time and cost.

BURROUGHS AUTOMATIC COMMUNICATIONS SYSTEM THE FOURTH GENERATION (BACS IV)

Charles 8. Modriulter In AGARD Real Time Computer Based Systems Dec. 1974 10 p (For svellability see N75-16257 07-82)

The design and development of a computer system architecture is reported for application to real time processing. The evionics multiprocessor system uses either a semiconductor memory or an integrated circuitry as a communication switch. Through the use of microprogramming, instruction sets unique to an application are created and stored in a control memory for interpretation.

N75-16273 Service Technique des Telecommunications de l'Air, Paris (France).

ORGANIZATION OF STRIDA (SYSTEM FOR PROCESSING AIR DEFENSE INFORMATION) [ORGANISATION DU STRIDA (SYSTEME DE TRAITEMENT DES INFORMATIONS DE DEFENSE AERIENNE)]

D. Coulmy In AGARD Real Time Computer Based Systems Dec. 1974 8 p in FRENCH (For availability see N75-16287 07-62)

A real time data processing system, STRIDA, for processing air defense information is reported. The system utilities a computer which processes data furnisher by rades and presents the deta to the controller. Data are included on the types of equipment, methods of programming, and the arrangement needed to insure satisfactory availability of the system.

PARALLEL COMPUTER WITH AUTOMATICALLY RECON-FIGURABLE ORGANIZATION (COPRA) [CALCULATEUR A ORGANISATION PARALLELE RECONFIGURABLE AUTOM-ATIQUEMENT (COPRA)]

M. C. Meraud and M. F. Browseys In AGARD Real Time Computer Based Systems Dec. 1974 5 p In FRENCH (For availability see N75-16287 07-62)

To meet the demand for reliability in digital computer data, a study was made to identify and solve the problems associated with such demands. The COPRA program is a structural arrangement which permits more confidence than is assessible by other technological means. Three fundamental mechanisms were utilized: a failure reconfiguration element which utilizes other equipment to share operations in case of performance degradation, an error detection element which inhibits the output of all errors in the results, and the resumption element which permits the continuation of the mission in cases after failure.

THE MECRA EXPERIMENTAL COMPUTER MODEL WITH AUTOMATIC RECONFIGURATION | LE MECRA MAQUETTE EXPERIMENTALE DE CALCULATEUR A RECONFIGURATION AUTOMATIQUE]

G. P. Germain In AGARD Real Time Computer Based Systems Dec. 1974 8 p. refs. In FRENCH (For availability see N75-16257 07-82)

A computer model supporting the study of diverse methods to increase reliability and sudurity in computer operations was examined. Several types of redundancies were put to work and the gains in reliability were evaluated. Reconfiguration methods were implemented and improvements of their effectiveness were tested. Experimental conclusions and calculated reliability are

included. The validity of all solutions are examined, in particular, aspects of placing the work under LSI technology.

SOME MULTICOMPUTER CONFIGURATIONS FOR RELIA-BILITY IN ATC SYSTEMS

J. Zuern In AGARD Real Time Computer Based Systems Dec. 1974 16 p. refs (For availability see N75-16257 07-62)

The experience in developing double computer systems with one computer operational and the other stand-by, showed that even for several systems with very different operational programs, the method for double computer monitoring and automatic switchover can be similar or the same for each. The method used in several applications is to have each computer aend in fixed time intervals appropriate status and control information to an independent unit. Several multicomputer ATC systems are discussed in detail to illustrate the effect of various data input and output availabilities and data storage reliability requirements. The experience with these systems has shown that the reliability improvements of each type meet the high requirements of ATC.

DISTRIBUTION OF THE TASKS IN A PHASED-ARRAY RADAR SYSTEM BETWEEN GENERAL-PURPOSE COMPUTERS AND SPECIAL PROCESSING UNITS

E. Hanie In AGARO Real Time Computer Based Systems Dec. 1974 7 p refs (For availability see N75-16257 07-62)

In a future radar system with an electronically steered entenna a lot of tasks must be handled aimultaneously with high speed, which do not run down with fixed parameters and independently from each others like in usual radar systems. The presentation shows, that in this multi-function processing system no units of the same kind can be implemented, since at particular points in the system data volumes of very different sizes and in verious time intervals occur. The steering of the different functions by data dependent parameters and the overall system control must

be handled by programmable general purpose computers, since during these control functions a lot of different data must be stored for a long time. Examples for that are given in the presentation, including implementation of graceful degradation.

FAULT-TOLERANCE FEATURES OF AN AEROSPACE
MULTIPROCESSOR

James S. Miller In AGARD Real Time Computer Based Systems Dec. 1974 p 9 refs (For availability see N75-16257 07-62)

Processor errors are detected by comparing results from duplaxed units executing concurrently. Local processor storage is also duplaxed, and sogregated from processing units. Parity offseking is used to identify the invalid copy when a comparison failure is signalled. Instruction execution is split into phases such that no phase overwrites its input. A hard-core redundant unit is used to command instruction-phase retry following a fault. If retry fells, another processor is interrupted to unload the faulty processor's local storage and prepare the disrupted process for immediate resumption at the point of failure. Recovery from faults in main memory capitalizes on the descriptor-based memory multiplexing scheme used for normal operation. A novel use of interleaving allows hardware-supported duplicated asfe storage of data segments in main memory, since these change too frequently to be duplicated on secondary storage.

THE DEVELOPMENT AND DEMONSTRATION OF HYBRID
PROGRAMMABLE ATTITUDE CONTROL ELECTRONICS

L. S. Smith and E. H. Kopf, Jr. /n AGARD Rea! Time Computer Based Systems Dec. 1974 10 p refs (For svallability see N75-18257 07-82) (Contract NAS7-100)

HYPACE provides an adaptable, analog/digital design approach that permits preflight and in-flight accommodation of mission changes, component performance variations, spacecraft changes, etc., through programing. This enabled broad multimission flexibility of application in a cost-effective manner. The HYPACE design, which was demonstrated in breadboard form our a single-axis ges-bearing spacecraft simulation, uses a single nontrol channel to perform the attitude control functions sequentially, thus significantly reducing the number of component parts over hard-wired designs. The success of this effort resulted in the concept being selected for the Mariner/Jupiter/Saturn 1977 apacecraft upplication.

THE ADVANCED SCIENTIFIC COMPUTER: AN ADVANCED
COMPUTER ARCHITECTURE AND ITS REAL-TIME APPLICATION TO BALLISTIC MISSILE DEFENSE

John W. Blakemore In AGARD Real Time Computer Based Systems Dec. 1974 12 p (For availability see N75-18257 07-83)

The advanced scientific computer (ASC) is a computer system utilizing three processing units, one optimized for control, one optimized for high speed arithmetic/logical operations on ordered arrays (called vectors) of data, and the third used exclusively for data transfers. This high throughput potential is due principally to the design of the control processor which permits continuous control operations without interferring with vector processing operations and to the fact that the ballistic missile defense problem provides vectors of data (on targets) in a natural way. The ASC control processor (through special hardware) is provided positive control over all elements of the system (i.e. memory, data channels, and the arithmetic /logical processor). It is implemented as eight independently programmable processors, each provided access to the entire memory space. The memory space may be implemented in allow or fast memory or a mixture of the two. The memory is all solid state, interleaved and overlapped, providing data to the processing elements at a maximum nominal rate of one word every six nanoseconds. Memory management, control, and protection is facilitated by the control processor special Author

Dale R. Youngs In AGARD Real Time Computer Based Systems Dec. 1974 12 p (For availability see N75-16257 07-62)

A small-size, high-performance, airborne-computer (IDP-974 General-Purpose Computer) was developed for application in an integrated display and processor system (IDPS) for lower-cost aircraft. The prime objective of this development was to optimize coet-effectiveness of the computer and primary displays subsystem by means of time-sharing the displays servicing, ballistics, navigation, etc., in a single central general-purpose computer. That is, the time-sharing of ballistics and navigation in the same computer is now commonplace, however, the additional task of real-time multiple displays servicing together with more sophisticated ballistics (the Hot-Line Air-to-Air mode) and navigation (multi-sensor mixing) required a sizeable increase in central computer performance. The availability of complex integrated circuits has made possible such increased performance in addition to decreased size and cost. The computer described herein averages more than 400,000 operations per accord and occupies a 1/2 ATR volume. In addition to merely high-speed, performance was increased further by virtue of a more versatile architecture. such as a large quantity of operational registers and complex instructions, than is normally found in low-cost computers.

PURPOSE PRE-PROCESSORS

A. Dimitriou In AGARD Real Time Computer Based Systems Dec. 1974 12 p (For availability see N75-16257 07-62)

Radio frequency signal processing for radar, ECM, acoustic, Loren, Nev-Set and other applications involves rapid sampling of the received signal and quick processing of the sampled data. Two approaches are possible when a digital computer is used for signal processing. One is to dedicate the computer to signal processing functions and allow other computational tasks to be performed as time permits. The other approach is to have a pre-processor or pre-processors operating under control of a central processing element. The pre-processor, in this case, performs the time consuming tasks of data sampling and simple manipulations of the sampled data. The data is then transferred to the central processor where more sophisticated processing is performed. This paper describes the control which is necessary in order for a pre-processor to operate under control of a central data processing element. Examined specifically, is the operation of a Loran-C pre-processor.

DEVELOPMENT EXPERIENCES OF REAL TIME COMPUTER BASED SYSTEMS IN STRIKE AIRCRAFT C. J. U. Roberts In AGARD Real Time Computer Based Systems

Dec. 1974 5 p (For availability see N75-16257 07-62) This paper will describe the nav/attack system that is fitted

to the UK version of the Jaguar aircraft with particular reference to its computing sub-system. The paper will also discuss the effect that the flexibility of digital computing has had on the flight trials program together with some of the salutary experience that has been gained on the inter-relationships of hardware and software and the need for a disciplined validation process for the flight program software.

N76-16292 International Business Machines Corp., Owego, N.Y. LAMPS: A CASE HISTORY OF PROBLEMS/DESIGN OBJECTIVES FOR AN AIRBORNE DATA HANDLING SUBSYSTEM

Rex Reed and Howard J. Cattle, Jr. (NADC, Warminster, Pa. In AGARD Real Time Computer Based Systems Dec. 1974 11 p (For availability see N75-16257 07-62)

This paper is presented to clarify and broaden the understanding of the problems relating to computer-based realtime systems. A purrent U.S. Nevy evionics data handling subsystem aboard a destroyer-based helicopter, will be reviewed as it progressed from the concept evaluation and flight test phases of an engineering test bed to the present engineering prototype. An analysis of the test bed's positive and negative data handling features are discussed with respect to their influence on the follow-on design. The prevailing philosophies and constraints surrounding such a development impacts the design alternatives while a balancing of hardware/software parameters assists in optimizing system performance. Finally, the Importance, even in the early design efforts of hardware/software cooperation is emphasized if an optimum design is to be achieved within the surrounding realities. Such early cooperation, as seen in the example, is felt to have optimized hardware design as well as eliminated much of the software required to reatify the lack of desirable, or even assential hardware features typical of independent design efforts. CONTROL (THE SOFTWARE STRUCTURE OF THE SYSTEM)

TEM)

R. Ehrmanntraut In AGARD Real Time Computer Based Systems Dec. 1974 14 p (For availability see N75-16257 07-62)

The system performs multi radar tracking on data from up to 6 radar stations. Extensive checks of data entering the system, especially for flight plans, are carried out. The system performs correlation of plans and tracks. Information in the data bank is automatically updated by radar. Technical particularities concerning the degree of modularity are discussed, and data bank structure and some supersignal security are discussed, and data bank structure. and some supervisory aspects are highlighted. It is shown that in the event of a hardware or software failure, a system reconfiguration will take place. In case the main computer falls, restart takes place from safe data on disk memory. Author

HOMOGENEOUS MEDIA

A. N. Ince /n AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 11 p refs (For availability see N75-22045 13-70)

A review of lectures on electromagnetic wave propagation is presented. The subjects of the papers are as follows: (1) development of models for electromagnetic propagation over rough surfaces, (2) electromagnetic propagation in layered guiding structures with irregular boundaries involving mode coupling and conversion, (3) remote sensing using an airhorne radar scatteromater and a noncoherent pulse radar on a stationary pistform, and (4) ground wave propagation over irregular and nonhomogeneous earth including land-sea boundaries, varying soil types, and mountain ridges.

N75-22047 Technische Hogeschool, Eindhoven (Netherlands). MATHEMATICAL THEORIES OF RADIO-WAVE PROPAGA-TION: AN HISTORICAL SURVEY
H. Bremmer In AGARD Electromagnetic Wave Propagation

Involving Irregular Surfaces and Inhomogeneous Media Feb. 14 p refs (For availability see N75-22045 13-70)

Mathematical models are developed to describe the characteristics of radio wave propagation. The purpose of the analysis is to determine the field strength due to a point source (the transmitter) placed in an homogeneous medium (the lower atmosphere), the field being observed on or slightly above an homogeneous sphere (the earth) and the electrical parameters of the two homogeneous media being known. The approaches considered are: (1) the Watson transformation, (2) the impedance boundary condition, (3) the effect of the horizontal etmospheric stratification, and (4) the statistical elements in wave propagation

N75-22048 Colorado Univ., Soulder. Dept. of Electrical MODELING OF ROUGH SURFACES

P. Beckmann In AGARD Electromagnetic Wave Propagation involving Irregular Surfaces and inhomogeneous Media Feb. 1975 10 p refs (For availability see N75-22045 13-70)

The theory of scattering electromagnetic waves by rough surfaces is analyzed in terms of the prediction problem and the probing problem. The models of central importance are identified ar those generated by random processes. The models can be reduced to two broad groups: (1) models using exact boundary conditions and an approximate evaluation (the Rayleigh method) and (2) models using approximate boundary conditions and accurate evaluation (the Kirchoff method). Both methods are capable of vectorization for treating the polarization of the scattered field in addition to its amplitude and phase.

NEW JUSTIFICATION FOR PHYSICAL OPTICS AND THE APERTURE FIELD METHOD

R. H. T. Bates In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media 1975 7 p. refs (For availability see N75-22045 13-70)

The extended boundary condition (optical extinction theorem) is used to examine the physical optics (Kirchoff) approximation to exact diffraction theory for scatterers of arbitrary shape having surfaces that can be usefully characterized by surface impedences. For inhomogeneous media with rough surfaces, without any asymptotic constraint on the shapes of the surfaces, the physical optics forms for the surface currents lead to estisfaction of the extended boundary condition deep inside the media, under fairly wide sets of conditions. The form of the incident field affects the goodness of the physical optics approximation. Flat surfaces have a special significance for physical optics. How to make use of ray-optical techniques to compute the equivalent surface currents on fictitious flat surfaces in front of the actual surfaces is discussed.

N76-22060 Harry Diamond Labs., Washington, D.C. a third-order specular-point théory for radar BACKSCATTER

James E. Seitzer In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media 1975 16 p refs (For availability see N75-22045 13-70)

Two principal modifications to the existing theory for electromagnetic backscattering from randomly rough surfaces with Gaussian height distributions are employed to extend the theory and make it more consistent with the physical optics solutions for reflections from curved surfaces. First, the geometrical optics solution for reflection from a point of stationary phase has been modified to include the contribution from the third-derivative terms in the power series expansion of the argument of the exponential in the Helmholtz integral thereby precluding the prediction of infinite backscattered fields from specular points that are also points of zero Gaussian ourveture. Second, the apptial densities of specular points have been determined as a function of the height coordinate with respect to the mean surface. in consonance with the latter development, height-dependent shadowing probabilities and means and mean-square values for the scattering amplitudes have been derived.

N75-22051 Texas A&M Univ., College Station ON VOLUME-DEPENDENT DEPOLARIZATION OF EM BACKSCATTER FROM ROUGH SURFACES

John W. Rouse, Jr. In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1976 5 p. refs (For availability see N78-22046 13-70) Recent investigations of the depolarization of backscatter of

coherent optical energy incident upon rough surfaces indicate that subsurface volume scatter is a primary depolarization mechanism. Measurements of inhomogeneous dielectric targets indicate that a depolarization ratio of unity is possible, i.e. total depolarization, and that the depolarized component is controlled almost exclusively by the degree of volume acetter within the sample. An extension of the physical optics approach has been formulated to incorporate contributions due to scattering within the subsurface volume. The study indicates that depolarization due to volume scatter is highly dependent upon the properties of the meterial; that volume scatter could govern the depolarization near vertical incidence; and that multiple surface scatter is most influential at incidence angles greater than 30 deg. The basic experimental work has been performed at optical wavelengths in the laboratory, however, sirborne microwave radar and radiometer measurements of sea ice have also been shown to exhibit a strong dependence on a volume scatter mechanism, This phenomens is apparently responsible for the excellent sea ice type differentiation observed in recent sensing studies

N75-22052 Naval Underwater Systems Center, New London,

SCATTERING FROM A SINUSOIDAL OCEAN SURFACE EXCITED BY A LONG, HORIZONTAL, ELECTRIC LINE

Dennis E. Fessenden In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1978 11 p refs (For availability see N75-22045 13-70)

The space wave electric field produced by a horizontal electric line source located above a traveling ocean surface is discussed. The ocean surface is approximated by a perfectly conducting, sinusoidal surface. Situations arise where the sinusoidal model is a good approximation of an actual ocean surface. For this case, the amplitude of the sinusoidal surface is small compared with a freespace wavelength; therefore, a Fourier integral-perturbation series approach can be used to solve the boundary value problem. The line source is oriented parallel to the crests and troughs of the sinusoidal ocean waves; thus, the problem is reduced to two dimensions and only one electric field component. The resulting space wave field is composed of the incident and specularly reflected field from a perfectly conducting.

flat surface plus a scattered term for the sinusoidal roughness. The magnitude of the scattered term is directly proportional to the sinusoidal surface amplitude in wavelengths, and Bragg scattering occurs for specific wavenumber relationships. Graphs are presented of the field variation as a function of the sinusoidal wave motion. Although the scatter theory was applied to a sinusoidal surface, it can be shown that the theory can be applied to any surface that is Fourier transformable.

N75-22053 Technische Hogeschool, Eindhoven (Netherlands). PROPAGATION THROUGH INHOMOGENEOUS AND STOCHASTIC MEDIA

H. Bremmer In AGARD Electromagnatic Wave Propagation Involving Irragular Surfaces and Inhomogeneous Media Feb. 1975 10 p. refs (For availability see N75-22045 13-70)

The propagation phenomena connected with the stochastic Inhomogeneity of the atmosphere are discussed. The theory relates statistical properties of the inhomogeneity with those expected for the field intensity fluctuations. Two quantities prove to be of dominating (importance; (1) the distance (D sub B) along which one single scattering is only to be expected and (2) the scale of turbulence, which is a measure of the inhomogeneity of the medium. The numerical values of these parameters fix the physical characteristics of the propagation in question. They can be represented by a point in a plot giving the penetration depth of the wave in the medium vursus the quantity D sub S. The various domains in this plot involve different propagation properties. Results are given which concern the variance and the distribution of the possible values of the irradiance for a wave that has covered a specified distance through the Author

PROPAGATION IN DUCTS AND WAVEGUIDES POSSESSING IRREGULAR FEATURES. FULL WAVE SOLUTIONS E. Bahar In AGARD Electromagnetic Wave Propagation Involving Irregular Surface and Inhomogeneous Media Feb. 1975 12 p refs (For availability see N75-22045 13-70)

The impetus to produce rigorous solutions to more realistic models of pertinent propagation problems over a wide frequency range has generated the need to derive full wave solutions to problems of india wave propagation in nonuniform multilayered structures. The considerable growth in civil and military interest in the development of more reliable communication and detection systems, the potential for developing radio wave methods for remote sensing and the need to develop hardened communication systems have contributed much to this renewed interest. These developments have been paralleled by remarkable advances that have been made in the availability of high powered, very low frequency electromagnetic sources that are capable of radiating deeper into the earth's grust as well as the availability of transmitters operating at optical frequencies. The ready access to large, versatile digital computers has made it possible to employ the full wave approach to obtain numerical solutions to a wide class of important problems which have hitherto been either ignored or over-idealized in order to reduce them to tractable

ASYMPTOTIC TECHNIQUES FOR PROPAGATION AND
SCATTERING IN INHOMOGENEOUS WAVEGUIDES AND
DUCTS

L. B. Felsen In AGARO Rectromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 5 p. refs (For svallability see N75-22045 13-70)

A ray-optical procedure of fairly recent origin provides new

physical insight and quantitative accuracy for model excitation and coupling due to localized sources or scatterers. The theory and several applications are reviewed. Concerning the ray-model conversion process, attention is given to the lateral ray shift associated with total reflection; this phenomenon has been a subject of interest in the recent literature on optics and integrated optics. The ray method is then extended to the tracking of inhomogeneous waves, thereby generalizing its applicability to evenescent fields, leaky waves and Gaussian beams. This more general theory is illustrated by Gussian beam propagation in a medium with transversely stratified refractive index, and by sostering of a Gaussian beam at a durved boundary. Some observations are made concerning the locality of propagation and scattering processes for homogeneous and inhomogeneous waves.

DIFFRRENTIAL FORMULAS FOR DIFFRACTION PRO-BLEMS IN THE RESONANCE DOMAIN FORMALISME DIFFERENTIEL POUR LES PROBLEMES DE DIFFRACTION DANS LE DOMAINE DE RESONANCE)

R. Petit In AGARD Electromagnetic Wave Propagation involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 11 p. refs. In FRENCH (For availability see N75-22045 13-70)

Differential procedures used to study diffraction grating problems of periodic surfaces are examined. In particular, partial differential equations, truncated Fourier series, Rayleigh hypothesis, and Halmholtz equations are discussed. Data gover application of conformal mapping to electromagnetic wave scattering by gratings, anomalies of diffraction gratings, scattering by uteleatric cylinders with arbitrary cross section shape, and optical grating couplers.

aCATTERING OUT OF THE EVAPORATION DUCT

S. Rotheram /n AGARD Electromagnetic Wave Propagation
Involving Irragular Surfaces and Inhomogeneous Media Feb.

1976 12 p refs (For availability see N78-22048 13-70)
The theory of beyond the horizon radiowave propagation in
the evaporation duct with a emooth sea surface and a smooth
refractive index variation is discussed, it has been shown that
the theoretical predictions nearly always exceed the experimental
values. It is postulated that this is a consequence of scattering
out of the duct by the rough sea surface and atmospheric
turbulence. A method is given for taking into account the rough
sea surface in which the smooth sea reflection coefficient is
replaced by a rough sea reflection coefficient of well-known form.
This is then converted into a surface impedance boundary condition
to be satisfied by the height-gain functions. Some numerical
results are presented and a preliminary comparison made with
experimental results.

PROPAGATION IN CURVED MULTIMODE CLADDED FISHES

W. A. Gambling, D. N. Payrie, and H. Matsumura /n AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 16 p (For availability see N75-22045 13-70)

An analysis is given of doupling between modes in curved, cylindrical, multimode optical fibers. The coupling coefficients are developed. The coupling characteristics of the various modes are developed. The degree of mode conversion is stated as largely restricted to a periodic exchange of energy, between the modes, along the length of the fiber with a periodicity which can be less than one millimeter. This form of quasi-single-mode operation is retreated in very low values of pulse dispersion, but is very sensitive to threas in the liber. The algnificance of these results in terms of mode conversion is discussed.

REMOTE SENSING OF SURFACE PROPERTIES
Albert Wayne Bloss of ACARD Blosser and ACARD Blo

Albert Wayne Biggs /n AGARD Electromagnetic Weve Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 12 p refs (For evallability see N78-22045 13-70)

A review of some experimental techniques used in remote sensing of the earth's surface is presented. The experimental techniques utilize remote sensing systems in sirborns and

stationary platforms. The remote sensing systems are on airborne radar scatterometer and a noncoherent pulse radar on a television tower at an altitude of 75 meters above the earth's surface. The results are presented in the form of the radar backscatter coefficient as a function of elevation angle. The forms of terrain are ocean surfaces, poles see lice and vegetation.

N75-22060 McDonnell Aircraft Co., St. Louis, Mo. POLARIZATION DISCRIMINATION IN REMOTE SENSING

J. C. Leader In AGARD Sectromagnetic Wave Propagation Involving Irragular Surfaces and Inhomogeneous Media Feb. 1975 12 p. refs (For availability see N75-22045 13-70)

Experimental measurements of the scattering cross section of various materials in both the microwave and optical spectrum have shown a complex behavior as a function of the experimental variables of polarization, frequency, and scattering geometry. Although it has long been recognized that the material variables of surface roughness and dielectric constant must in some fashion govern the material's scattering properties, a complete description of observed scattering behavior in terms of only these variables has not, to date, proved possible. There are numerous examples of multi-polarization radar imagery which have defied an adequate interpretation in terms of material surface scattering properties alone, particularly with regard to anomalies in the co-polarized and cross-polarized returns. Although polarization sensitive remote sensing using active sources in the optical spectrum is in its infancy, a similar state of confusion regarding interpretation may be expected unless a better understanding is available regarding fundamental scattering characteristics. Theoretical and experimental works which provide a basis for explaining many observed acattering characteristics are reported. This explanation is inade possible by including the effects of volume scattering as a re-radiation source. The experimental data provided result from optical measurements; however, corresponding agreement between theory and experiment has also been shown in the microwave spectrum.

N75-22061 Neval Research Lab., Weshington, D.C THE SECOND ORDER DOPPLER SPECTRUM OF RADAR SEA ECHO FOR FREQUENCIES ABOVE VHF

G. R. Valenzuela In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975—11 p. refs (For availability see N75-22045—13-70)

The effect of surface tension in the second order Doppler spectrum of radar see echo is investigated. The analysis includes the angle of incidence dependence, the polarization dependence, and the lossy-dielectric properties of the see. Surface tension is introduced in the hydrodynamic part of the transfer coefficient. The introduction of surface tension in the analysis allows for resonant interactions of the gravity-capillary wave components on the water surface. Numerical results are presented from the generalized theory for vertical and horizontal polarization as a function of radar wavelength, wind speed, and radar viewing angle in relation to the wind direction.

N75-22062 Kansas Univ., Lawrence. VOLUME SCATTERING FROM ICE AND WATER IN INHOMOGENEOUS TERRAIN

Albert W. Biggs. In AGARD. Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media. Feb. 1975. 13 p. refs (For availability see N75-22045. 13-70).

Volume scattering of electromagnetic waves from Arctic sea ice and terrain with varying amounts of water is considered. Physical properties of sea ice and disjectric properties of snow are described in terms of mixtures of ice and water and the Debye relaxation spectra of water at microwave frequencies. Scatturing models include brine pockets in sea ice, ice spheroids in glacial snow, and varying amounts of water in snow and ice. Radar backscatter measurements of sea ice and SLAR images are interpreted with these models. Three models of volume scattering are described. The first model is developed from Lambert's Law, which indicates that light scattered from a radiating surface varies in intensity as the cosine of the propagation direction and the surface normal. The second is made by replacing the terrain by a single layer of spheres, which scatter equally in all cirections. The third model considers many layers of spheres. The apheres of ice are treated as Enton lenses, which yield a much higher scattering cross section than that of a perfectly conducting metal sphere of the same size.

THE PROPAGATION OF RADIO WAVES THROUGH PERIODICALLY VARYING MEDIA

G. F. Lyon and A R. Webster In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 d p refs (For availability see N75-22045 13-70)

The propagation of radio waves through periodically varying media is discussed by treating ionospheric irregularities as perturbations in a smooth ionosphere with a normal electron density versus height profile. It is possible in this way to model any shape or size of irregularity and to predict from the model any change in the number of electrons along any ray path and any angular deviations due to the perturbation. The method is illustrated by modelling periodic irregularities associated with Travelling ionospheric Disturbances and the findings are compared with some experimental observations.

A technique is presented for remote probing a stratified medium using a spectral domain approach which differs from the conventional time-domain technique. The magnitude and phase of the field at the surfaces of the inhomogeneous medium when the probing wave is from the free space region of x less than zero is determined. The value of the measured surface makes it possible to compute the spectral domain counterparts which must be processed to determine the value of x. The computer storage and processing time for this procedure are within the capability of minicomputers. Several numerical results for profile functions are included to illustrate the utility of the method.

Giovanni Dauris and Domenico Solimini In AGAAD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975—13 p refs (For availability see N75-22045—13-70)

A method for identifying the geometry of atmospheric irregularities is illustrated and its use in an experiment is described. The method consists in determining the spatial statistics of the field in a transverse plane at the receiving and of a line-of-sight propagation path. The spatial statistics are derived by measuring the degree of coherence for points aligned in vertical and horizontal directions. By the anisotropy of the coherence, the geometrical structure of irregularities of the part of atmosphere which has been passed through is inferred. By taking a mentage of the observation of other quantities that the interferor wirld technique can provide, the diverse mechanisms of propagation are recognized, thus confirming the existence of a given structure of irregularities. The experiment has been conducted at X-band over a 37.5 Km path, and data which have been obtained from it furnish, among other things, information on the probability of occurrence of mateorological conditions related to the observed structures of irregularities.

N75-22066 Manitoba Univ., Winnipeg. Dept. of Electrical Engineering. RADIOMETRIC SIGNATURES OF COMPLEX BODIES

M. A. K. Hamid In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhormogeneous Media Feb. 1976 27 prefs (For availability see N76-22045 13-70)

The basic theory for microwave radiometric signatures of finite stationary or moving, matallic or non-metallic, bodies of simple shape which are either larger in extent than the beam coverage of the radiometer entenna or lie entirely within the beam is outlined. The theory is developed to illustrate modeling concepts by deriving a correction factor due to the finite dimensions or structural inhomogeneities of the body and is extended to few composite bodies which can be viewed as combinations of simple ones. Experimental results for the emission pattern of selected objects are also presented to show the

interaction between the physical parameters of the target and the electrical parameters of the radiometer.

N78-22067 Coloredo Univ., Boulder. Cooperative Inst. for Research in Environmental Sciences. REVIEW OF GROUND WAVE PROPAGATION OVER NON-UNIFORM SURFACE

James R. Wait In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 20 p. refs (For availability see N75-22045 13-70)

A consolidated review of recent analytical studies of electromagnetic waves propagating over inhomogeneous surfaces is presented. Emphasis is on smooth boundaries that can be characterized by a local surface impedance. A general integral equation formulation is developed for this situation. A number of special cases are then considered and various methods of solution are described. Various concrete, practical examples are presented, particularly with regard to effects that occur at coastlines. Extensions to certain types of terrain features are also treated using the closely related mode matching method. Some controversial aspects of very recent work on the subject are described.

SURFACE IMPEDANCE OF RADIO GROUNDWAVES OVER STRATIFIED EARTH

P. Hoekstra, A. Delaney, and P. Sellmann. In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media: Feb. 1975. 8 p. refs (For availability see N75-22045.13-70).

Ground and airborne techniques to obtain subsurface information, for geotechnical objectives, by measuring the surface impedance of radiowaves have been developed. The frequency range covered in these measurements is from 14.7 Khz (VLF) to 660 Khz (BCB). Messurements in the North America Ardiic have shown that it is common to encounter changes in the effective resistivity with frequency from several thousand chm-m at VLF to a few tenths of ohm-m at BCB. These changes are caused by a conductive organic layer over highly resistive frozen ground. Also large regional and local changes in surface impedance were observed. In the permefrost regions changes from 6000 ohm-m to 50 ohm-m at VLF were found to occur frequently over distances of about 100 m. Surveys at VLF on the ground resolve discontinuities in ground conditions over distances of a few meters. Author

PROPAGATION OVER PASSIVE AND ACTIVE NONUNIFORM SURFACE IMPEDANCE PLANES

R. J. King and S. H. Cho (Wiscons a Univ.) In AGARD Electromagnetic Wave Propagation Involving Inregular Surfaces and inhomogeneous Media Feb. 1975–16 p. refs (For availability see N75-22045-13-70) (Grant NSF GK-21218)

Electromagnetic wave propagation over and radiation from nonuniform surface impedance planes are studied by numerical methods using the integral formulation of the compensation theorem. The source is a horizontal magnetic line current and the surface impedance is assumed to only very in the direction of propagation and have a magnitude less than the intrinsic impedance of free space. Otherwise it is unrestricted. It is shown how the Sommerfeld attenuation function for propagation over a uniform surface can be used to piecewise explain and predict the general behavior of a wave propagating over a nonuniform surface. It is used to determine impedances which support fast or slow, and growing or decaying traveling waves. This gives general guidelines for manipulating the complex surface impedance to achieve specified radiation characteristics, or alternatively, field distributions on the surface. The integral formulation is then used to study microwave surface wave antennas. By varying the profile of the surface resotance magnitude and the antenna length, the radiation characteristics such as directivity, beam width and side labe level can be optimized. Author

ANALYSIS OF GROUND WAVE PROPAGATION OVER

IKREGULAR, INHOMOGENEOUS TERRAIN

R. H. Ott. /n AGARD. Electromagnetic Wave Propagation Involving Irragular. Surfaces and Inhomogeneous Media. Feb. 1875. 6 p. refs. (For availability see. N75-22045 ; 3-70).

A numerically feasible way to calculate the field strength of a radio wave propagating over realistic, smoothly verying, inhomogeneous terrain has been developed. The terrain risk be represented by a completely arbitrary profile in terms of the elevation versus distance, and the conductivity and dielectric constant may change continuously along the path. One of the features of the surface wave that has been predicted by the numerical solution is a strong focusing phenomenon on lit portions of concave hills. This focusing phenomenon can also be explained in terms of Fock currents for concave surfaces. An example is given where the Fock currents on an equivalent parabola are used to predict the focusing on the lit side of a Gaussian hill. The numerical solution is then applied to a practical engineering problem; showing the effect of terrain features on the efficiency of HF antennas for launching and receiving surface waves over the sea. It is shown that, in general, placing the antenna at the top of the hill may be less efficient than placing it at the coastline, but placing it halfway up the hill may be more efficient than at either the hillton or the coastline.

N75-22071 Shape Air Defense Touhnical Center, The Hague (Natherlands). Communications Div. GROUND-LOSS PROFILE ALONG A MULTI-SECTION PATH OF A SKY WAVE

J. C. Arnbak. In AGARD. Electromagnetic Wave Progragation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975. 10 p. refs (For availability see N75-22045.13-70).

For medium- and high-frequency waves radiated by ground-based antennas at low grazing angles, the far field is highly dependent on properties of the ground along the path of propagation. Notably, the conductivity and ground irregularity inside the first Freenel zone, which typically extends to about one hundred wavelengths in the direction of propagation, affect the strength of the field transmitted to (or received from) distant points. An engineering method to evaluate the associated path loss of a vertically polarized sky wave in the presence of a plane, sectionally homogeneous ground is discussed. The influence of randomly rough surfaces is considered. The section model allows a profitable combination of stendard ground data with a fast, numerical extension of simple mixed-path theory. Author

ANYENNA AND CONDUCTING SCREEN ON A LOSSY GROUND

J. F. Goodsy /n AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 17 p refs (For availability see N75-22045 13-70)

1975 17 p refs (For availability see N75-22048 13-70). The problem of a vertical monopole situated over a small, circular, highly conducting screen lying on a poorly conducting ground has been considered. The electromagnetic field of the system is obtained via a Green's function expansion in oblate spheroidal wave functions. By integrating the outward power flow over the surface of the antenna and the apherical surface at infinity the radiation and loss resistances of the antenna are obtained. Antenna resistances were obtained experimentally in the H.F. band. Radiation patterns were measured at 3 GHz (using a carbon loaded dielectric material to simulate the behavior of soil at 30 MHz) and their areas used to calculate antenna radiation resistances. The results obtained are applied to the case of an electrically small untuned receiving monopole feeding directly

into a transistor amplifier to examine the signal to noise ratio of such a system. It is concluded that although the use of an imperfect ground system can result in a marked reduction in radiation resistance for small screen sizes the effect of the corresponding loss resistance upon the signal to noise ratio is not expected to be significant in the H.F. band.

PROPAGATION OF A LORAN PULSE OVER IRREGULAR, INHOMOGENEOUS GROUND

J. Raiph Johler and Samuel Horowitz (AFCRL, Bedford, Mans.) In AGARD Electromagnetic Wave Propagation involving Irregular Surfaces and Inhomogeneous Media Feb. 1975—13 p. refs (For availability see N75-22045—13-70)

A numerical solution of an integral equation representation of the ground wave over irregular, inhomogeneous earth has been employed to calculate amplitude and phase of the propagated continuous wave as a function of frequency. A computer simulation again using numerical methods, transforms this result to the time domain yielding the impulse response. Then the impulse response is convolved with the Loran-C pulse function, that has been transformed from the time domain to the frequency domain. The propagation of both pulse envelope and the cycles under the envelope in the presence of irregular, inhomogeneous ground is demonstrated. Although the Loran-C pulse propagation has been studied in detail, the method is applicable to the propagation of most any shape pulse over irregular, inhomogeneous ground. In the particular case of the Loren-C pulse, the discrepancy or time difference between the pulse envelope and cycle is a unique function of the particular type of terrain over which the wave propagates, and it is, at the present state of the art, necessary to introduce such terrain into the propagation theory to give a unique prediction of the pulse propagation time.

N75-22075 Army Electronics Command, Fort Monmouth, N.J. Communications/Automatic Data Processing Leb. THE BEHAVIOUR OF LORAN-C GROUND WAVES IN MOUNTAINOUS TERRAIN

Douglas C, Pearce and John W. Walker In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 9 p refs (For availability see N75-22045 13-70)

The behavior of both the horizontal H-component and the vertical E-component of a Loran-C ground wave has been measured in the violnity of an isolated terrain enomaly. Nittany Mountain, near State College, Pennsylvanis. Time difference measurements were made with Army manpack receivers at 42 sites of good geodetic control in the area. The magnetic component of the ground wave was sensed with a ferrite array antenna while the vertical component was sensed with a whip antenna. Significant local warpages of the loran grid, apparently associated with the presence of the mountain, were observed with each antenna configuration. However, the warpage patterns were not identical for each field component, implying a somewhat different perturbation of each polarization component by the terrain anomaly. These results suggest that a field calibration of a loran grid in a region of a terrain anomaly will depend somewhat on the antenna type used.

SPATIAL AND TEMPORAL ELECTRICAL PROPERTIES DERIVED FROM LF PULSE GROUND WAVE PROPAGATION MEASUREMENTS

Robert H. Doherty /n AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 17 p. refs (For availability see N75-22045 13-70)

Low frequency ground wave phase measurements made on two loran (100 kHz pulse trensmissions) paths have been analyzed for spatial variations. One Loran-D path in Nevada and California passes over Death Valley producing a so called Death Valley Anomaly. The other 1000 km Loran-C baseline path between Carolina Beach, N. C. and Dana, Indiana was measured in detail during the spring of 1970. Four locations in addition to the transmitter locations were monitored, one near Carolina Beach (the master), one just east of the Appalachian Mountains, one just west of the Appalachian Mountains and one near Dana, Indiana (the Z slave station). Effective surface impedance values were deduced for each segment of the propagation path. In

addition to these spatial evaluations of the phase, temporal variations of the phase over the eastern path were approximately one microsecond, even though synchronization accuracies were better than .1 microseconds. Changes in the surface impedance values as a function time are clearly indicated.

SERVICE AREA PREDICTION IN THE VHF AND UHF

H. Page In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 8 p refs (For availability see N75-22045 13-70)

An analysis of the factors which affect the prediction of terrestrial transmitter performence in very high frequency and ultrahigh frequency bands is presented. The main fastures that determine field strength at a particular point are as follows: (1) terrain irregularities, (2) terrain features such as buildings and trees, (3) scattering of signals by local obstacles when the antenna is low, (4) temporal variations, and (5) multipath propagation. Methods for using these factors in conducting an analysis of electromagnetic propagation and scattering are proposed.

PREDICTION AND CALCULATION OF TRANSMISSION LOSS IN DIFFERENT TYPES OF TERRAIN

A. Biomquist and L. Ladell In AGARD Electron,₂gnetic Weve Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 17 p refs (For availability see N75-22045 13-70)

A model for the calculation of transmission loss in the VHF and UHF regions has been developed, it has been used in service area predictions in different types of irregular terrain in Sweden with much better results than the existing models. The method is very easy to handle and needs no complicated computer technique, it takes proper account of the ground delectric constant and the terrain profile including vegetation. It is thus a deterministic model giving the long-term median of the basic transmission loss. In planning terrestrial radio systems it is also necessary to have a knowledge of the variability in time and with location. On that account measurements are presented giving the additional loss for various percentages of time and locations. The best possible use of the capacity of telecommunication systems is often limited by the depolarization produced by absorption and scattering in the terrain. The effect of depolarization is given for various percentages of locations.

MIXED-PATH CONSIDERATIONS FOR RADIO-WAVE PROPAGATION IN FOREST ENVIRONMENTS

Train: In AGARD Electromagnetic Wave Propagation involving irregular Surfaces and inhumogeneous Media Feb. 1975 11 p refs. Sponsored in part by ECOM and Army Land Warfare Lab. (For availability see N75-22045 13-70)

The propagation of radio waves is examined for communication paths that may lie partly within a forest and partly in the air region outside the vegetation. For this purpose, the geometry of a mixed path involving a forest layer adjacent to a bare-ground area is shown to exhibit four characteristic regimes. If, for example, the transmitting antenna is inside the forest, these regimes correspond to the receiving antenna being located in one of the following regions: (1) inside the forest; (2) above the tree tops: (3) at a relatively high sititude above the bare-ground region; or (4) at a relatively low height above the bare-ground region. Depending on frequency, on distances, and on which one of the four regimes is involved, the predominant field along the mixed path may be a refracted wave or a lateral wave. By finding the conditions that determine which one of these waves is predominant, it is possible to establish path losses in practically any regions involving reasonably flat ground contours. The frequency range of application for these considerations extends well into the VHF region. Author

INFLUENCE OF TOPCGRAPHY AND ATMOSPHERIC REFRACTION IN UHF GROUND-AIR COMMUNICATIONS

A. N. Ince and H. P. Williams In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 26 p refs (For availability see N75-22045 13-70)

The results of field strength measurements in UHF ground-sir communication using four different ground terminals are presented. The local conditions at the ground terminals varied considerably: in one case the site was flat and clear over a distance of 2 km, in another the site was flat and clear over a distance of 2 km, in another the site was the highest in the district, a third site had nearby buildings, while the fourth site had marked local undulations and a nearby valley. In all four cases the field strength at the optical horizon was very close to the theoretical value for a smooth earth. The field strength at this point was virtually unaffected by the local ground conditions. Using this fact, and taking into account the statistics of atmospheric refraction it is possible to predict the reliability of UHF ground-to-air communication for high-flying aircraft.

FLIGHT TEST RESULTS OF PROPAGATION EXPERIMENTS THROUGH INHOMOGENEOUS MEDIA

Allen L. Johnson In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975. 7 p (For availability see N78-22045 13-70)

Flight test evaluation of communication systems to determine the effect of the inhomogeneous propagation media on com-munication reliability is discussed. The approach taken has been to postulate a physical or mathematical model and then to collect data to determine the validity of the hypothesis. Two related areas which have been studied are ducting and radio holes. Both are caused by an inversion layer. Ray tracing studies were done to establish expented performance under various atmospheric conditions. Data was then gathered on an air-to-air microwave system to validate the model. The test results showed good correlation between predicted and actual results when sufficiently detailed refrective index information was available for the predictions. Two other phenomena investigated were ionospheric edintillation and multipath fading. In the case of ionospheric scintilistion the model is not well defined, and the test results were used to refine the model. The test results from the multipath fading flight testing showed that for over-water communications a specular reflection model best defines the actual results while over-land the diffuse fading component is predominant.

MULTIPATH IN AN AERONAUTICAL SATELLITE SYSTEM

H. J. Wuennenberg In AGARD Electromagnetic Wave Propagation Involving Irregular Surfaces and Inhomogeneous Media Feb. 1975 18 p refs (For availability see N75-22045

13.70)

The multipath problem as encountered in a civil aeronautical satellite system is analyzed. A model for the multipath reflection is developed and the performance of the communications channels through the satellite is evaluated. The seronautical satellite system will be used to control air traffic over the Atlantic and Pacific oceans. Aircraft will fly at a height of 10 to 20 km. Severe impairment of the communications performance is expected due to reflection of radiowaves from the surface of the sea and inadequate protection by the aircraft antenna against multipath. A simple theoretical model for reflections from the sea is developed. Under the assumption that only very simple coding schemes can be used to improve the bit error rate for digital transmissions the application of frequency diversity, space diversity and time diversity is discussed. It is shown that frequency diversity is more suitable for the link from the satellite to the aircraft while space diversity can be used for the link from the alroraft to the satellite. The application of time diversity does not reduce the bit error rate by a great amount because of correlation between consecutive bits, it is shown that large delays' between messages are necessary to make time diversity attractive. Time diversity would therefore lead to coding by blocks and to storage requirements.

EXPERIMENTAL EVALUATION OF FLUCTUATING DENSITY AND RADIATED NOISE FROM A HIGH-TEMPERATURE JET

P. F. Massier, S. P. Parthasarathy, and R. F. Cuffel. In AGARD Noise Mech. Mar 1974 19 p refs (For availability see N74-22840 14-02) (Contract NAS7-100)

An experimental investigation has been conducted to characterize the fluctuating density within a high temperature (1100 K) subsonic let and to characterize the noise radiated to the surroundings. Cross correlations obtained by introducing time delay to the signals detected from spatially separated crossed laser beams set up as a schlieren system were used to determine radial and axial distributions of the convection velocity of the moving noise sources (eddies). In addition, the autocorrelation of the fluctuating density was avaluated in the moving frame of reference of the eddies. Also, the autocorrolation of the radiated

noise in the moving reference frame was evaluated from cross correlations by introducing time delay to the signals detected by spatially separated pairs of microphones. The radiated noise results are compared with Lighthill's theory and with the data of Lush. Radial distributions of the mean velocity were obtained from measurements of the stagnation temperature, and stagnation and static pressures with the use of probes

DIRECT MEASUREMENT OF SOUND SOURCES IN AIR JETS USING THE CROSSED BEAM CORRELATION TECHNIQUE

R. J. Damkevala, F. R. Grosche (DFVLR-AVA Goettingen, W. Germany), and S. H. Guest. //2 AGARD. Noise Mech. Mar. 1974 16 p refs (For evailability see, N74-22640 14-02) (Contract NASS-27011)

Properties of density fluctuations were measured in the turbulent regions of a 2.54 cm air jet, at M = 0.7, 1.0 and 1.94. After calibration tests, it was found that the absorption of infrared radiation at 4.3 microns by the naturally present quantities of carbon-dioxide in air was directly proportional to the air density if a sufficiently wide bandpass (0.08 microns) was used. Moreover, regions of the band could be selected that adequately discriminated against temperature variations. The cross-correlation of two such beams intersecting in the jet gave a measure of the local properties at the intersection point A derivation is presented relating the local density correlation function to the self and shear generated noise in the far field of the jet. The measured correlations are used to predict the exial eulo selon fo murbage that bne ettignarie source for notificial to a unit volume of turbulence.

N74-22646 Deutsche Forschungs- und Versuchsanstalt füer Luft- und Raumfahrt, Goettingen (West Germany). DISTRIBUTIONS OF SOUND SOURCE INTENSITIES IN SUBSONIC AND SUPERSONIC JETS

F. R. Grosche In AGARD Noise Mech refs (For availability see N74-22640 14-02) Mar 1974 10 p

Clues on the validity of serodynamic noise theories can be provided by comparison of predicted distributions of sound source intensities in turbulent jets with source distributions determined directly by suitable acoustic measurements. A method of tracing the sound sources from the sound radiated into the acoustic far field was developed. The sound waves emitted by a small volume. of the jet are focused upon a microphone well outside the flow by means of a large elliptical mirror. The distribution of sound source intensities is investigated by moving the mirror-microphone. assembly along and normal to the jet axis. Results of measurements with subsonic and supersonic jets show interesting details of the noise generation within these jets

CORRELATIONS BETWEEN FAR FIELD ACOUSTIC PRES-SURE AND FLOW CHARACTERISTICS FOR A SINGLE AIRFOIL

M. Sunyach, H. Arbey, D. Robert, J. Bataille, and G. Cornte-Bellot. In AGARD, Noise Mech. Mar 1974, 12 p. refs (For availability) see N74-22840 14-021

A NACA 8512 A sub 10 airfoil, whose chord is 8 cm, was placed in a uniform flow and ducted into an anechoic chamber with a speed ranging from 20 to 40 m/s. Its acquatic far field was analyzed in relation with the normal velocity fluctuations in the wake and the pressure fluctuations on the airful surface. Cross-correlations measurements showed that the aerodynamic pattern close to the trailing edge, on the extrados, controls the noise emission

N74-2264B Office National d'Etudes et de Recherches Aerospatiales, Paris (France). REPRESENTATION OF HOT JET TURBULENCE BY MEANS

OF ITS INFRARED EMISSION

Jeun Francois DeBelleval and Mariano Perulli in AGARD Noise Mech. Mar. 1974 10 p. rofs. In FRENCH, ENGLISH summary (For availability see N74-22640 14-02)

The theoretical description of a jet acoustic radiation is usually described by characteristic turbulance data, defined at the scale of the total emissive volume. These data are deduced from theoretical models or from measurements making use of correlation techniques. These data have average values in time representing the whole spectrum. After a discussion on the nature of acoustic sources which may exist in a hot jet, and after

recalling the crossed beam techniques, a representation of a hat jet turbulence by means of crossed spectral densities is presented. It is then possible to define at any point of the source volume the characteristic turbulence data by frequency bands. and thus to know their dispersion.

N74-22549 British Columbia Univ., Vancouver. Dept. of Mechanical Engineering NOISE SOURCE DIAGNOSTICS USING CAUSALITY CORRELATIONS

Thomas E. Siddon. In AGARD. Noise Mech., Mar. 1974, 13 p. refs (For availability see N74-22640 14-02) (Grants NRC A7108, DRB-G-9611-03)

Due to the complex mix of noise mechanisms for current quieter generations of sircraft, it has become more difficult to detect the small changes in overall decibel level which may result from localized design modifications. An increasingly popular diagnostic technique establishes causative relationships between individual noise source phenomena and the oversil (composite) sound radiation. The method uses real-time cross-correlations between the far field sound pressure and fluctuating physical parameters occurring in, on, and around the noise generating machine. The technique is based on established seroacoustic theory and has been shown to yield information on acoustic source distributions, their local spectra, and scales of coherence The basic causality formalisms are reviewed and their use illustrated by reference to a number of proven exparimental applications. It is shown that by judicious choice of control surfaces the methods can be adapted in unique ways to the elucidation of a number of unresolved noise generation and suppression phenomena Examples pertaining to jets, suppressor nozzles, rotating fan bisdes, and flow interaction with leading and trailing edges are included.

USE OF CROSS-CORRELATION MEASUREMENTS TO INVESTIGATE NOISE GENERATING REGIONS OF A REAL JET ENGINE AND A MODEL JET

W. C. Meucham and P. M. Hurdle. In AGARD. Noise Mech. Mar. 1874 13 p refs Sponsored by NASA (For availability see N74-22640 14-02) CSCL 20A

Cross-correlations are reported of the let static pressure fluctuations (as measured with a B and K microphone fitted with a nose cone), with the far-field radiated sound pressure. These measurements were made for various probe positions and a large number of far-field positions (at various angles). In addition, the tests were run for a number of different jet exit velocities. The measured, normalized cross-correlation functions vary between 0.004 and 0.155. These values depend upon the angular position of the far-field microphone, the jet exit Mach number, and the position of the probe. In addition, the cross-correlation technique was employed to study the symmetry of the far-field radiated sound about the jet axis. Third-octave analyses of both the probe signal and the far-field radiated sound were made. This is the first time correlation measurements have been made on a jet ongine. In addition, a report is given on an extensive noise survey of a model jet. The correlations are related to sound source functions and jet source regions are discussed.

SOME EXPERIMENTAL OBSERVATIONS OF THE REFRAC-TION OF SOUND BY ROTATING FLOW
G. D. Butler, T. A. Holbeche, and P. Fethney In AGARD Noise

Mech. Mar 1974 10 p refs (For availability see N74-22640

Some experimental and theoretical studies of the Interaction of cound with a rotating flow field in the form of an aerodynamic vortex are described. The experiments were carried out in the acoustically-treated working-section of the RAE 24-foot diameter open-jet wind tunnel. Vortices were generated by setting a sharp-edged wing at incidence in the tunnel airstream and the effect of the vortex flow downstream of the wing trailing-edge on the noise propagating from a small loudspeaker source was investigated over a range of frequencies and wind speads. Considerable refractive redistribution of the sound energy by the vortex flow occurred, leading to far field regions of markediv decreased and increased sound intensity. Qualitatively, these effects are consistent with the predictions of ray theory, although the interaction persisted down to frequencies where ray theory

might be regarded as inapplicable. Some possible reasons for the observed differences with theory are briefly discussed.

N74-22852 General Electric Co., Schenectady, N.Y. Mechanical Engineering Lab. THE ISSUE OF CONVECTIVE AMPLIFICATION IN JET

NOISE Ramani Mani In AGARD Noise Mech. Mar. 1974 12 o

Sponsored in part by Air Force (For availability see N74-22840 14-02)

Three problems of the sound power and power spectrum produced by moving acoustic sources shrouded by jet flows were considered. The jets were assumed (for simplicity) to be characterized by a slug flow or top hat type mean velocity profiles. The sources were simple harmonic in their own frame of reference and were assumed to convect with the same velocity as the jet. The first problem considered the case of a monopole source convecting along the axis of a round jet. The second problem considered the case of convected line sources in a plane or two-dimensional jet. This was motivated by the need to understand the effect of off-axis lines of convection. The last problem was a variation of the first wherein the jet density and temperature are allowed to differ from those of the ambient. It was motivated by the need to understand the noise from heated jets. The studies were all motivated by one notion, namely, that Lighthill's original idea of ascribing jet noise to convected sources radiating freely to the ambient needs revision to allow for mean flow shrouding effects. The studies explain several experimentally observed features of jet noise such as a failure to exhibit convective amplification (particularly at high frequencies and shallow angles to the exhaust axis) and associated failure to peak frequencies in the power spectrum to shift linearly with jet velocity. Implifications for the jet density exponent issue for heated jets were also considered. The study may be regarded as moving sources solutions to the Phillips equation for jet noise with a specific velocity profile, namely the top hat profile. The advantage of choice of a simple velocity profile is to obtain solution valid for arbitrary frequencies.

THE NOISE FROM SHOCK WAVES IN SUPERSONIC

M. Harper-Bourne and M. J. Fisher In AGARD Noise Mech. Mar. 1974 13 p refs (For availability see N74-22640 14-02)

A theoretical model is proposed for the prediction of the characteristics of broadband shock associated noise from lets operated above the critical pressure ratio. The model regards each shock cell and as a source of acoustic radiation with relative phasing set by the time of eddy convection between them. This leads to a prediction for the peak frequency of this noise component as a function of both pressure ratio and angle of observation which is amply confirmed by experimental results. The model is also extended to the prediction of the spectrum of shock associated noise and these predictions are also compared with experimental date it is also shown that the intensity of shock noise is a function only of pressure ratio, and is independent of jet stagnation temperature and hence jet efflux velocity.

NOISE FROM HOT JETS

P. A. Lush and M. J. Fisher In AGARD Noise Mech. Mar. 1974 8 p refs (For availability see N74-22640 14-02)

Measurements of the noise from several independent workers of hot subsonic lets show that the noise decreases relative to the unheated jet at high jet velocity but increases at low velocity. The decrease at high velocity has previously been explained by the reduction in the jet density for the hot jet and this explanation is confirmed by the present study. The increase in noise at low velocity is attributed to an additional source caused by entropy fluctuations which varies as U4 compared with U8 for the usual mixing noise. A simple theoretical model using Lighthill's theory of serodynamic sound is proposed and this gives very good agreement with the experimental results, but the theoretical model cannot be justified rigorously. However it could provide a satisfactory method for prediction of the noise from hot jets and a basis for the collapse of data. Author

ON THE NOISE FROM JETS

G M Lilley In AGARD Noise Mech. Mar 1974, 12 p. refs. (For availability see N74-22640 14-02)

A modification of Lighthill's theory is discussed in which pressure disturbances in the let are treated as an inner flow problem which is matched to the outer flow radiation problem. In this treatment the source function involves quadratic and higher order small disturbance terms. This approach, elthough more complicated mathematically than the exact theory of Lighthili. has the advantage that it draws attention directly to the role played by the mean velocity and temperature distributions on the generation and propagation of the emitted sound. The model in its simplest form can be reduced to a vortex sheet model and thus draws attention to the stability characteristics of the vortex sheet. In the more general treatment the stability characteristics of the mixing region are considered and its least stable modes are regarded as dominating the large-scale eddy motion. The linear stability theory is extended to deal with non linearities and, as a result, the amplitude of the larger-scale motion is determined. This is compared with the measured large-scale structure of the jet. From this model the main characteristics of the source function are found. The paper concludes with some results from this new formulation and a comparison is made with experimental findings.

N74-22666 Imperial Coll. of Science and Technology, London (England). Dept. of Mathematics. MECHANISMS OF EXCESS JET NOISE

D. G. Crighton In AGARD Noise Mech. refs (For evallability see N74-22640 14-02) Mar. 1974 7 p

The second secon

Excess noise is a term used to describe the deviations of measured noise fields from the predictions of Lighthill's theory of pure jet mixing noise. A definition is given for the current state of theoretical understanding of those excess noise fields which are not directly attributable to rotating machinery, or to shock waves in supersonic jets. It is shown that unsteady flow interaction with the jet pipe can generate intense forward arc and sideline noise levels, while abnormally high rear arc levels are suggested to arise from the propagation of genuine sound fields suross the exit plane, with associated refraction and diffraction effects. A further process, not yet properly quantified, is related to the instability of a (fully turbulent) jet to certain preferred large scale disturbances, and leads to a mechanism (perametric amplification) by which internal sound fields may be greatly augmented in either the rear or forward arcs. EXPERIMENTS CONCERNING THE FLOW DEPENDENT ACOUSTIC PROPERTIES OF PERFORATED PLATES
Juergen Kompenhans and Dirk Honneberger In AGARD Noise

Mech. Mar. 1974 6 p. refs (For availability see N74-22640 14-02)

The results are presented of investigations of the influence of grazing flow on the impedance of a single crifice serving as a simplified model of a perforated plate. At small flow velocities the impedance curve plotted in the complex plane passes through a spiral. For higher flow velocities the resistive part of the impedance increases linearly with the flow velocity whereas the reactive part decreases. A relation between the impedance and the static flow resistance can be established. Possible nonlinear properties of the prifice are discussed. Author

A DETERMINISTIC MODEL OF SONIC BOOM PROPAGA-TION THROUGH A TURBULENT ATMOSPHERE

B. H. K. Lee and H. S. Ribner In AGARD Noise Mech. Mar. 1974 13 p. refs. Prepared in cooperation with Toronto Univ. Ontario (For availability see N74-22840 14-02)

The propagation of a weak normal shock wave through a turbulent atmosphere is studied in terms of an idealized model. The turbulent field is assumed to be weak and represented by the superposition of two inclined shear waves of opposite inclination to the mean flow. The resulting flow is of a cellular nature. The cells are rectangular in shape and the sense of rotation of the flow alternates from call to call. If the angles made by the normal of the incident shear waves with the direction of the mean flow are greater than some critical value an exponentially decaying pressure wave is generated behind the shock Spiked or rounded waveforms are obtained by adding or

subtracting this pressure wave from the steady state pressure field. An illustrative example for a mean flow Mach number of 1.0005 is considered. This gives a steady state overpressure of 2.45 lb/ft sq across the shock which is typical of the overpresmond place a ni mus Author

SONIC BOOM BEHAVIOR NEAR A CAUSTIC

Frank Obermeier In AGARD Noise Mech. Mar. 1974 14 p. refs (For availability see N74-22840 14-02)

The pressure signature is analyzed of an ideal N-shaped sonic boom caused by an accelerated projectile. Its signature in the surroundings of the so-called caustic and behind the caustic is discribed by the equations of linear wave acoustics. The calculations are performed for a special case where the acceleration phase is chosen in such a way that the corresponding Mach-cone, modified by the acceleration, is composed of a truncated cone, the lower part of which has a circle like curved surface and the upper part is ordinary straight cone. The proposed theory yields results which are in good agreement with measure-Author ments.

RECENT STUDIES INTO CONCORDE NOISE REDUCTION R. Hoch and R. Hawkins (Rolls Royce, Ltd., Bristol, Engl.) In AGARD Noise Mech. Mar. 1974 14 p. refs. Prepared in cooperation with Rolls Royce, Ltd., Bristol, Engl. (For availability see N74-22640 14-02)

Recent research is summarized which was conducted over the past two years as part of a continuing noise reduction program on the Concorde powerplant. The studies were simed at: (1) improving knowledge of certain noise sources of the Olympus 593 turbojet engine and (2) evaluating potential means for noise reduction either at source by alteration to the various entine components, or by addition of attenuating devices. Some of the results of the studies have been applied to the powerplant design standard intended for entry into service, others are mentioned only for their technical or didactic interest, and others after engineering avaluation, may lead to acoustic improvements to the Concorde powerplant after entry into service.

AEROSONIC GAMES WITH THE AID OF CONTROL ELEMENTS AND EXTERNALLY GENERATED PULSES

L. J. Poldervaart, A. P. J. Wijnands, and L. Bronkhorst. In AGARD Noise Mech. Mar. 1974. 4 p. refs (For evaluability see N74-22640.

Experiments were conducted which indicate that with the aid of control elements, it is possible to generate the following modes of vibration of a 2-dimensional sonic jet: (1) zero mode; (2) oscillatory mode, natural and forced; (3) pulsatory mode; and (4) coupled pulsatory-oscillatory mode. The experiments also demonstrated that with the aid of externally generated pulses. it is possible to show how the information, near the nozzle tip, is transferred from the pulse into the jet. The nozzle tip as a discontinuity proves to be a dominant factor in the interaction process of the pulse with the boundary layer and with the jet.

ON THE GENERATION OF JET NOISE

J. Laufer, R. E. Kaplan, and W. T. Chu. In AGARD. Noise Mech. Mar. 1974. 8 p. refs (For availability see N74-22840

(Grant DOT-OS-00002)

It is proposed that the rate of subharmonic production, that is, the rate at which large scale vortex-ring like structures interact with each other, is the primary mechanism responsible for most of the noise generation of a subsonic jet. The interaction consists of simultaneous acceleration and deceleration of vorticity containing coherently moving regions followed by a pairing process. This picture is consistent with Lighthill's quadrupole like sources, as well as with the formulation of Powell's vortex sound theory. It is suggested that more direct experiments are necessary to examine the validity of the above proposition.

AN EXPERIMENTAL STUDY OF THE INTERMITTENT WALL PRESSURE EURSTS DURING NATURAL TRANSITION OF A LAMINAN SOUNDARY LAYER

Fred C. DeMetz and Mario J. Casprella In AGARD Noise Mech. Mar. 1974 18 p. refs (For availability see N74-22640 14-02)

The properties of the intermittent well pressure field were measured in the transition boundary layer on a large flat plate in an anechoic wind tunnel. Natural transition was achieved with a mild favorable pressure gradient at Reynolds numbers, based on downstream distance from the plate's leading edge, in excess of 7 million. The development of the isminar boundary layer prior to transition was in agreement with numerical solutions to the laminar boundary layer equations and with stability criteria for pressure gradient effects. The temporal spatial, and spectral properties of the transition wall pressure field associated with the natural transition process occurring on the plate are obtained as a function of the intermittency fantor, and compared with those of the fully turbulent pressure field. Specifically, the mean-square pressure, spectral densities, convection velocities, distributions of burst periods and burst rates of the intermittent pressure field are computed from the data.

ON THE INTERACTION BETWEEN A SHOCK WAVE AND A VORTEX FIELD

A. Naumann and E. Hermanns In AGARD Noise Mech. Mar. 1974 10 p. refs (For availability see N74-22640 14-02)

In a double side shock tube, the flow pattern produced by the interaction of a weak shock wave with a vortex field was observed by means of Mach-Zehnder interferograms; the vortex direulation and the pressure ratio of the shock were varied. An evaluation of the interferograms gives the time dependent density fields. The deformation of the interacting shock leads to a discontinuity in slope of its front and to the formation of a secondary wave from the sharp bending point. With the assumption of linear superposition, the flow pattern is in very good agreement between the theoretical and experiments

INVESTIGATION OF THE INSTANTANEOUS STRUCTURE OF THE WALL PRESSURE UNDER A TURBULENT BOUND-ARY LAYER FLOW

R. Emmerling, G. E. A. Meier, and A. Dinkelacker. In AGARD Noise Mech. Mar. 1974 12 p refs (For availab:\text{\text{lty see}} N74-22640 14-02)

An optical method was used to investigate the instantaneous structure of the wall pressure under a turbulent boundary layer flow in air. The optical apparatus consisted basically of a Michelson-interferometer. One mirror of the interferometer was replaced by a reflecting flexible wall, which was also part of the wall bounding the flow being investigated. The turbulent wall pressure fluctuations cause the flexible wall to be displaced by several light wave-lengths. The instantaneously occurring fringe patterns were recorded with a high-speed film camera. The wall area observed was 48 mm x 29 mm, and the flow velocity outside the boundary layer was 8.5 m/sec. The optical method used made it possible to determine the instantaneous values of the wall pressure distribution, the convection velocity and the vail pressure gradient.
